Pima Indians have a high prevalence of obesity, diabetes mellitus and hyperinsulinemia, but they have low plasma cholesterol levels, reduced LDL synthesis, and greatly decreased incidence of cardiovascular disease. VLDL metabolism in Pima Indians will be investigated in order to further investigate lipoprotein metabolism in this population. Synthetic and catabolic rates for VLDL will be compared in groups having different insulin levels using tritiated glycerol as a precursor. VLDL metabolism will be studied in a group diabetics to determine the influence of hyperglycemia on VLDL metabolism in this population. Conversion of VLDL to LDL will be studied using 125I VLDL and 131I LDL simultaneously. Postheparin, muscle, and adipose tissue lipoprotein lipase levels will be measured. The results of this study should yield data on VLDL metabolism and its conversion to LDL in this population and explore the relation between these lipoproteins and cardiovascular disease.

COMPLICATIONS AND OUTCOME OF DIABETIC AND PREDIABETIC PREGNANCIES

P.H. Bennett, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Arthritis Metabolism & Digestive Diseases, Southwestern Field Studies Section, *Phoenix, Arizona* 85016 (Z01 AM 69001-11 EFS)

To determine the effects of diabetes mellitus and prediabetes on the complications and outcome of pregnancy in women in the Gila River Indian Community.

The characteristics of all pregnancies among residents of the Gila River Indian Community will be determined. Each pregnant woman will have a modified glucose tolerance test during the third trimester and following delivery and will be retested at approximately two yearly intervals in conjunction with the prospective study of diabetes mellitus in the same community. The characteristics of the pregnancies in women who subsequently become diabetic will be compared to those among women who were diabetic at the time of pregnancy and those who remain nondiabetic.

HEMOGLOBIN A1 LEVELS IN DIABETES

S.L. Aronoff, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Arthritis Metabolism & Digestive Diseases, Phoenix Clinical Research Section, *Phoenix, Arizona* 85016 (Z01 AM 54021-03 DD)

Glycosylated hemoglobin (HbA1) concentrations were measured in 600 Pima Indians, aged 15 to 91 years, who were participating in the epidemiological studies of diabetes in the Gila River Indian Reservation in Arizona. At the same time plasma glucose

levels, fasting and two-hours post-glucose load (75 g), were determined and the plasma glucose values were compared with HbA1 levels in the same population to assess the utility of HbA1 measurements in the diagnosis of diabetes. The distribution of glucose levels in Pimas has been described previously by a model of two overlapping Gaussian curves. Attempts were made to fit the same model to the HbA concentrations. For patients aged 25 years and over, the frequency of HbA1 levels were bimodally distributed and, like the glucose levels, satisfactorily fit the overtapping Gaussian distribution model. These observations indicate the presence of two subpopulations in the Pima Indians, one normal and one diabetic. HbA1 levels in the nondiabetic portion of the population were found to increase as a function of age in the Pimas, as expected. Levels of HbA1 were highly correlated with both fasting and two-hour post-load plasma glucose values, but did not discriminate better than the glucose data between diabetic and nondiabetic subjects.

STUDIES OF PATIENTS WHO ARE CHRONIC CARRIERS OF HEPATITIS B SURFACE ANTIGEN HBSAG

J.H. Hoofnagle, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Arthritis Metabolism & Digestive Diseases, Liver Diseases Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 AM 53509-02 DDB)

Persons with HBsAg-positive chronic hepatitis are being enrolled in a prospective study of this disease. Thirty persons have been entered into this study, 22 of whom have been followed for at least I year (and 8 for 2 years . 20 patients have had liver biopsies. At the start all except one patient had elevated serum aminotransferase levels and all were HBsAg positive; 27 had HBeAg and 24 DNA-polymerase detectable in serum. On follow-up, one has lost HBsAg but 8 have lost HBeAg. These who seroconverted from HBeAg to anti-HBe have also had a spontaneous clinical remission with disappearance of all symptoms and a return of serum aminotransferase levels to normal. The remaining patients, who are persistently HBeAg-positive, have had stable levels of HBsAg, HBeAg and aminotranserases. In individuals with stable hepatitis B virus markers, trials of antiviral agents are being planned. Initially I0-I5 persons are being treated with adenine arabinoside monophosphate (Ara-AMP). Because there is a natural spontaneous rate of remission in this disease a controlled clinical trial will be planned in the event that Ara-AMP seems to be effective against the hepatitis B virus.

LONG-TERM STUDY OF ASYMPTOMATIC AND FUTURE DIABETES

S.S. Fajans, University of Michigan, Ann Arbor Campus, Medical School. Dept. of Internal Medicine, *1335 E. Cathenne St., Ann Arbor, Michigan* 48104 (R01 AM 00888-26)

This is a continuing long-term project in which a large number of nondiabotic relatives of diabetic patients, as well as asymptomatic mildly diabetic patients are being studied periodically. We hope to learn more about the natural history of various types of diabetes mellitus from the points of view of: 1) genetics, 2) possible environmental factors, 3) carbohydrates intolerance, 4) insulin secretion, 5) other pancreatic hormone secretion, 6) occurrence of pancreatic islet cell antibodies, 7) HLA antigen types, 8) development of microangiopathy, 9) development of macroangiopathy, 10) development of neuropathy, 11) evaluation of factors which alter the expression of these manifestations.

LONGITUDINAL STUDY OF A PRE-OSTEOPOROSIS POPULATION

R.P. Heaney, Creighton University, School of Medicine, Dept. of Medicine, *629 N. 27th St., Omaha, Nebraska* 68131 (R01 AM 07912-17)

This project consists of a 20-year prospective study of the population-at-risk for osteoporosis. Research subjects are 199 normal women, who were aged 35-45 at the start of the study six years ago. Observations are made once every five years and consist of comprehensive calcium kinetic, calcium metabolic and metabolic and physiolgical measurements, as well as radiogrammetric and photo densitometric measurement of bone mass. A total of 90 primary and derived variables is accumulated on each subject. The purposes of the project are: 1. To obtain comprehensive longitudinal data on calcium metabolism, bone metabolism, and related physiological functions in a group of untreated women from the perimenopausal period to the median onset time of osteoporotic symptoms; 2. Thereby to provide an exhaustive physiological profile both on women who develop symptomatic osteoporosis, and on those who do not, allowing characterization of the differences between them and of the factors influencing the differences; 3. Thereby to permit better identification of the osteoporosis-prone subset and to provide both a rational basis for prophylactic treatment and the identification of subjects who should be its target; 4. And finally, to characterize cross-sectional interrelationships between major physiological variables during this key era of osteoporosis development.

THE ROLE OF VIRUSES IN RENAL TRANSPLANT PATIENTS

H.H. Balfour, University of Minnesota, Minneapolis Campus, School of Medicine, Dept. of Laboratory Medicine & Pathology, *1305 Mayo, Minneapolis, Minnesota* 55455 (R01 AM 18883-05)

Preliminary retrospective studies at our institution have indicated an association between viral infections and acute febrile illness, transplant rejection and mortality. However, the following have not been answered satisfactorily: 1) What is the source of the patient's virus? 2) Do viruses cause clinically relevant illness? 3) How do viral infections relate to immune function and episodes of rejection? Our objective is to answer these questions by performing an intensive prospective epidemiologic viral study. The source of virus will be sought by examining serologic studies of donors, transplant staff, and age-matched blood donors. The relationship of viral shedding with clinical illness will be examined by prospective studies with frequent viral culturing and detailed clinical/observations. Specimens will also be examined by immunofluorescence and counterelectrophoresis for evidence of viral antigens. Nonspecific and specific humoral and cell-mediated tests will be done to investigate the relationship of viral infection to immune function, and these studies will be correlated with episodes of rejection. Routine tests will include quantitation of T and B cells, a battery of viral antibody titers, mitogen stimulation using PHA and Con A, and mixed lymphocyte culture. Tests for CMV-specific cell-mediated immunity have been developed and are being used prospectively as indicators or predictors of the presence and severity of CMV infections.

ESTROGEN EFFECTS ON BILIARY LIPIDS & BILE ACID KINETICS

F. Kern, University of Colorado, Health Sciences Center, School of Medicine, Dept. of Medicine, *4200 E. 9th Ave., Denver, Colorado* 80262 (R01 AM 19605-03S1)

The objectives of this proposal are to define the mechanisms of the secretion of lithogenic bile which underlie the increased incidence of cholesterol gallstones in women, especially during the child-bearing age and among those taking contraceptive steroids; to determine the effect of pregnancy, the norami ovulatory cycle and contraceptive steroids on biliary lipid composition, bile acid kinetics, cholesterol secretion and gallbladder function and to relate these effects to changes in naturally occurring female sex hormones; and to seek means of restoring biliary lipid composition to normal and reducing cholesterol cholelithiasis in the above group of patients.

Biliary lipid composition and secretion, bile acid kinetics and gallbladder function will be measured in pregnant women, women during the normal ovulatory cycle, women receiving contraceptive steroids and in appropriate control groups. Bile-rich duodenal fluid will be used. For the kinetic studies, bile acids will be labeled with either the stable isotope, 13C or the radioactive isotope, 14C, depending upon the study group. Appropriate serum female sex hormone concentrations will be determined at the time of study and will be correlated with changes in biliary lipids and bile acid kinetics, etc. The capecity of phenobarbital, salicylates and possibly other agents to modify the estrogen effects will be tested in animals.

LYME ARTHRITIS - A NEW EPIDEMIC DISEASE
A.C. Steere, Yale University, School of Medicine, Dept. of Internal Medicine/Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (R01 AM 20358-04)
Lyme disease, a tick-transmitted, immune-mediated, epidemic disorder in children and adults, usually begins in summer with a characteristic skin lesion, erythema chronicum migrans, that may be followed weeks to months later by meningoencephalitis, peripheral neuritis, myocarditis, or by migratory, intermittent or chronic arthritis. We plan to define the natural history of this illness--its prognosis and treatment--etiology, vector, and pathogenesis. To accomplish these objectives, a network of primary physicians has been established to refer patients with recent onset of the illness. The natural history of the disease will be described from the serial examination of these patients. The possible pathogenetic role and interactions between circulating immune complexes, lymphocyte function, and immunogenetic determinants will be explored in selected patients. Epidemiologic field studies of patients, the implicated vector, I. dammini, and its animal hosts and environment will be done on 2 islands to determine the natural cycle of the disease. In an effort to identify the causative agent, ticks collected from the field will be identified by stage and species, pooled, and inoculated into monkeys, Peromyscus leucopus, and embryonated hens' eggs. Tick pools and their salivary glands will be reacted with convalescent sera by indirect immunofluorescence and by radioimmunoassay. If the agent can be identified, a serologic test for diagnosis will be developed, and attack rates will be determined within sample human and animal populations. The results would provide the basis for decisions about control measures.

3.0968,
RISK FACTORS FOR AGE RELATED HIP FRACTURES
L.J. Melton, Mayo Foundation, *200 1st St. S.W., Rochester, Minnesota* 55901 (R23 AM 28377-01)
The focus of this proposal is the quantification of clinically-evident risk factors for age-related proximal femur fractures as they occur in a community. The results of this study will provide the data needed to design an effective prevention program, by delineating the high-risk patient groups who could most profit from detailed assessment and subsequent prophylactic measures. These data are not presently available and, as a result, organized preventive efforts are essentially at a standstill.
The specific factors to be studied have been suggested by previously published research or identified in preliminary studies here. The epidemiologic case-control study proposed will help clarify which of the factors are significantly associated with hip fractures, which have the greatest potential impact on community hip fracture rates, which occur long enough before the fracture to permit effective intervention, and what proportion of the hip fracture population can be identified through these factors. The present proposal is also the key to future epidemiologic studies of age-related fractures in the community.
Rochester is an ideal setting for this type of research because most of the biases that bedevil case-control studies elsewhere can be obviated here. Medical care for the population of Olmsted County, Minnesota, is almost entirely provided by the Mayo Clinic and the Olmsted Medical Group and their affiliated hospitals. The records of these institutions and other providers have been assembled into a single diagnostic retrieval system and comprise a unique resource for population-based epidemiologic studies. Thus we can identify complete incidence cohorts of patients with hip fractures and can find matched controls who are representative of the general population. Exposure data are available from accurate and detailed contemporary medical records of long duration.

3.0969,
EPIDEMIOLOGY OF BONE LOSS, OSTEOPOROSIS AND FRACTURES
B.L. Riggs, Mayo Foundation, *200 1st St. S.W., Rochester, Minnesota* 55901 (R01 AM 27065-01)
Our objective is to make epidemiologic studies on age-related bone loss, osteoporosis and fractures in female residents of a circumscribed community (Rochester, Minn.). These studies have been made possible by our modification of the dual photon absorptiometry method to permit direct measurement of bone density of the spine and proximal femur (coef. variation is less than 3%) at actual fracture sites, rather than, as has been the case in the past, indirect estimates from measurements of the appendicular skeleton. We plan to apply this methodology to an age-stratified random sample of 300 females to estimate the distribution of bone density levels in the population and prospectively to 200 patients incurring nontraumatic hip or spine fractures. The number of these fractures occurring at each level of bone density will be related to the expected number of women with these levels of bone density in the community population in order to calculate the relative risk of spine or hip fractures at each bone density level. Also, 100 normal female subjects within 20 years postmenopausal will be followed for 4 years with serial measurements to determine rates of bone loss. All subjects having bone density measurements will be interviewed to assess pertinent social, medical, nutritional and behavioral data and will have hormonal and biochemical determinations on blood and urine samples. Serum hormonal determinations will include vitamin D metabolites, immunoreactive parathyroid hormone, immunoreactive calcitonin and sex steroids (including free estradiol and free testosterone). From these data, we will identify those selected variables which best discriminate between women with high and low levels of bone density, women with high and low rates of bone loss and women with and without fractures of the hip and spine. This will permit characterization of those postmenopausal women who are at the highest risk for excessive bone loss and for spine and hip fractures and, therefore, would be candidates for prophylactic therapy. Such information could be used to develop guidelines essential for cost-effective national health care programs to reduce the occurrence of age-related fractures.

3.0970,
ETIOLOGY OF CROHN'S DISEASE
K.M. Das, Yeshiva University, Bronx Campus, Albert Einstein School of Medicine, Dept. of Medicine, *1300 Morris Park Ave., Bronx, New York* 10461 (R01 AM 26403-02)
We wish to define the etiology of Crohn's disease, in particular, the role of the transmissible agent in causing this disease. The objectives are: (1) to use athymic mice (nu/nu) to study the putative transmissible agent, (2) to isolate and characterize the putative agent from human and nu/nu tissue.
Using nu/nu, our initial studies are unexpected and exciting. Crohn's disease lymph node homogenate from 9 different patients induced malignant lymphoma in nu/nu whereas control lymph node homogenated did not. Electron microscopic examination of the tumors and one lymph node homogenate from a patient with Crohn's disease showed presence of virus particles by thin sectioning and negative staining with phosphotungstic acid. Two lymphomas ae being cultured in vitro and both of them are B cell lymphoma.
We intend to extend these observations using a large number of nu/nu to examine the reproducibility, specificity, effect of dosage of the materials injected, and to culture the lymphomas both in vivo and in vitro. We will also study antigenic recognition in the lymphoma and other internal organs of the nu/nu (e.g., liver, spleen, intestine) using immunofluorescent techniques and appropriately absorbed sera from patients with Crohn's disease and control subjects. Similar recognition will be investigated in established lymphoid cell lines from nu/nu lymphomas. Replication of the virus will be examined using cocultivation techniques with established cell lines (e.g., WI-38 and lymphoid cells). Both human and animal tissue will be examined by electron microscopy for detection of specific virus by conventional methods and negative staining. Further characterization of the virus will be performed by plaque, enzymatic and radiolabelling assays.

3.0972,
COMPARISON OF OVERWEIGHT AND OBESITY AS RISK FACTORS
J. Habicht, Cornell University, Ithaca Campus, New York State College of Human Ecology, Division of Nutritional Sciences, *Ithaca, New York* 14850 (R01 AM 26236-02)
The first aim of the project is to develop a critique of current methods of assessing overweight as a risk factor in epidemiological studies, and to define valid procedures for evaluating the performance of these methods. The second aim is to develop a model of body weight in a large population sample as a function of body composition, expressed in anthropometric and demographic variables. The third aim is to examine the relationships of (1) weight-height indices, (2) obesity and body composition, and (3) other aspects of physical configuration, to the risks of diabetes and of hypertension. The purpose is to ascertain what empirical effects the theoretical problems of indices have on risk estimates for two diseases believed to be associated with overweight, and to see if the aspects of body composition and configuration which affect risks of disease can be identified more accurately. An overall goal is to make specific recommendations for using anthropometric measurements (including weight and height) to assess risk factors in chronic disease in adults.

PATHOGENESIS OF PORPHYRIA CUTANEA TARDA
B.F. Felsher, University of California, Irvine Campus, California College of Medicine, Dept. of Medicine, *Irvine, California* 92664 (R01 AM 26008-02)
The proposed studies are designed to elucidate the role of genetic and environmental factors in the pathogenesis of porphyria cutanea tarda.
The incidence of familial porphyria cutanea tarda in a large group of patients with this disease will be determined by measuring urinary uroporphyrin concentration, fecal isocoproporphyrin concentration, and red cell uroporphyrinogen decarboxylase activity in all the available first degree relatives of these patients. These values will be compared to our previously determined normal values, as well as those obtained in clinically non-porphyric subjects with alcoholic liver disease, subjects with hepatic siderosis, and all the available first degree relatives of these subjects. The effects of the chronic administration of alcohol on hepatic and red cell uroporphyrinogen decarboxylase activity will be studied in rats.

GENETIC EPIDEMIOLOGY OF DIABETES IN RUBELLA DEAFNESS

W.E. Nance, Virginia Commonwealth University, School of Basic Sciences & Graduate Studies, Dept. of Human Genetics, *901 W. Franklin St., Richmond, Virginia* 23284 (R01 AM 25786-02)

A three-year study will be conducted to determine the prevalence of metabolic and immunologic indices of islet cell damage and/or glucose intolerance in a cohort of adolescent children with rubella embryopathy in relation to the maternal and offspring HLA phenotypes. The study will thus exploit the naturally occurring paradigm of isletopathy in 6,000 children with congenital rubella who were born during the 1964-65 pandemic to test the general hypothesis that diabetes can arise from a gentically determined adverse host response to viral infection either in the affected individual or in the mother during pregnancy. The study will further define the rubella syndrome and could lead to the identification of specific maternal factors that are of importance in the etiology diabetes and birth defects. Longitidinal observations of blood glucose and insulin response to a standard oral glucose challenge will be obtained along with C-peptide assays, insulin antibody determinations, Hb Alc measurements and screening for auto-antibodies to islet cells and other tissues. These studies, along with HLA typing, will permit an accurate characterization of the type of juvenile diabetes that occurs in the rubella syndrome as well as providing evidence as to whether immunologic abnormalities can precede or only follow the onset of glucose intolerance in this high-risk population.

DIABETES IN THE PACIFIC-GENETIC-ENVIRONMENT INTERACTIONS

P.Z. Zimmet, Royal Southern Memorial Hospital, Dept. of Metabolic Medicine & Epidemiology, *260 Kooyong Rd., Box 185 Caulfield S., Melbourne, Victoria, Australia* (R01 AM 25446-02)

The specific objectives of this project are to determine: (a) whether specific genetic markers exist in the maturity-onset diabetic (NIDDM) or in individuals who have predisposing genes for diabetes. (b) whether the differing susceptibility of various ethnic groups to maturity-onset diabetes is related to the presence or absence of these genetic markers. (c) to establish the relative role of other factors such as age, nutrient intake, physical activity, obesity, stress, etc. in the causation of diabetes in genetically susceptible individuals. (d) the definition of possible preventative factors relating to diabetes in high prevalence populations. On the basis of these findings it is hoped that intervention programmes might be undertaken.

It is hoped to achieve these objectives by measurement of genetic markers (e.g., tissue typing, red blood cell enzymes and serum proteins with known gene loci). The studies will be carried out on Caucasian, Melanesian, Polynesian, Micronesian, and American Indian populations.

Such a study provides a broad spectrum of ethnic groups with varying susceptibility to diabetes. It will allow the comparison of genetic and various environmental factors which may influence the development of diabetes in these populations.

DYSPEPSIA, PEPTIC ULCER AND ITS COMPLICATIONS

J.H. Kurata, University of California, Los Angeles Campus, School of Public Health, Dept. of Epidemiology, *405 Hilgard Ave., Los Angeles, California* 90024 (R01 AM 25330-02)

This study will examine and further elucidate the epidemiology of peptic ulcer disease and dyspepsia. Three samples will be drawn from patients from the VA Wadsworth clinics: 100 men with duodenal ulcer; 100 men with dyspepsia negative to all tests; and 100 control men without any history of ulcer disease, matched to the duodenal ulcer cases on the basis of age and race. Risk profiles will be developed for each of these groups. The dyspeptics negative to all tests will be compared with the duodenal ulcer cases and the controls to determine if this group, or a subset, can be considered as representing a pre-ulcer population. Comparisons of the risk profiles of the three groups will be made--the risk profiles will be based on demographic characteristics, genetic markers, psychosocial risk factors, medical history, and biochemical variables. An attempt will be made to develop a classification scheme based on risk profiles and to determine if there is an identifiable subset of patients with dyspepsia negative to all tests who could be regarded as having a mild and/or pre-ulcer condition.

In addition, conducted by means of a subcontract to Los Angeles County Harbor General Hospital (under Dr. Jerome I. Rotter) an investigation will be made of the interaction of the genetic and environmental factors in peptic ulcer.

JUVENILE DIABETES MELLITUS - EPIDEMIOLOGY & ETIOLOGY

A.L. Drash, Childrens Hospital of Pittsburgh, *125 De Soto St., Pittsburgh, Pennsylvania* 15213 (R01 AM 24021-03)

The incidence of J.O.D. less than 16 years of age will be determined for the first time in a defined community. The incidence will be related to age, sex, race and geographic area of residence. Seasonal and temporal trends will be evaluated. Secondary cases of J.O.D. within families during a 10 year follow up will be identified. The interrelationship of the demographic characteristics with HLA type, immunoglobulin and autoantibodies within and between families will be measured. Genetic analysis will include analysis of both immediate and extended families and will include HLA typing, immunoglobulin and autoantibody studies. The distribution of glucose tolerance within the families in relation to immunology, genetic and epidemiological characteristics will be considered. Viral antibody studies at the time of the initial diagnosis of a case within a family and prior to secondary case will be also be included. These studies should help determine the interrelationship of host and environmental factors in the etiology of J.O.D.

RISK FACTORS IN GLUCOSE INTOLERANCE

M. Modan, Chaim Sheba Medical Center, Dept. of Clinical Epidemiology, *Bitan 27, Tel Hashomer, Ramat Gan, Israel* (R01 AM 23080-02)

OBJECTIVES: A. Overall: 1. General: To attempt to quantify the interrelationships, distinguish between causes and consequences, evaluate the relative role of environmental and genetic factors and understand the temporal sequence of events in the complex of glucose intolerance - obesity - macro and micro vascular complications. 2. Specific: A nationwide sample of 5600 Jewish residents, born 1912-1941, stratified by sex, age, place of birth and length of residence in Israel is being followed prospectively in three phases. In phase I (1968-72) ten consecutive once-daily blood pressure measurements, weight, height and morbidity information were collected on each individual at home. In phase II, (which started at the end of 1976), about 1500 phase I participants were examined for oral glucose tolerance (OGT), urea, ECG, weight, morbidity and mortality. Phase III, (1979-current grant, comprises four parts: Main study: consists of examinations of 4000 phase I participants by the main set of examinations namely: the above listed phase II examinations as well as determination of glycolsylated hemoglobin (HbA1) insulin response curve (IRC), high, low and very low density lipoproteins (HDL, LDL, and VLDL) and creatinine. Dietary study: About 1200 detailed dietary interviews in all overt diabetics and a sample of persons with chemical diabetes and with normal glucose tolerance. High molecular weight proteinuria study: In the dietary study group presence of high molecular weight proteinuria will be determined. Drug study: In an estimated 600 persons on oral hypoglycemic and/or antihypertensive drugs, urine, and serum drug concentrations will be determined for assessment of compliance, factors affecting response to these drugs and the interrelation of drug therapy with morbidity.

VITAMIN B12 TRANSPORT AND ITS DISORDERS

R. Carmel, University of Southern California, School of Medicine, Dept. of Medicine, *2025 Zonal Ave., Los Angeles, California* 90033 (R01 AM 23027-03)

Three distinct areas of research are planned, which all deal with vitamin B12 transport and its relation to various diseases and abnormalities of such transport. The first study deals with the role of the pancreas in vitamin B12 transport, and involves the delineation of the nature and composition of normal and abnormal human pancreatic secretions in relation to vitamin B12. It is hoped thereby to clarify the role of the pancreas in vitamin B12 absorption and malabsorption. The second area of study involves the characterization of a macromolecular transcobalamin which is ubiquitous in human serum but about whose nature and function very little is known. The third area deals with an extensive analysis of clinical, laboratory and epidemiological data compiled on the large, heterogenous patient population with pernicious anemia at LAC-USC Medical Center. Particular attention will be paid to potential subgroups within this disease entity. In addition it is planned to analyze gastric juice from such patients with an intrinsic factor radioimmunoassay to be developed to better define the nature of the defect in various types of pernicious anemia and gastritis. Methodology to be used in all the above studies includes use of electrophoretic, chromatographic, and immunologic techniques, and cell uptake studies using various in vitro cell systems.

BONE QUALITY CHANGES IN HUMANS - A 20-YEAR FOLLOW-UP

A.N. Milner, Texas Womans University, College of Nutrition Textiles & Human Development, Dept. of Nutrition & Food Sciences, *Box 23925, Denton, Texas* 76204 (R01 AM 21518-03)

Approximately 1,000 persons who underwent bionutritional and medical tests (including radiographs of the hand and os calcis for x-ray bone mineral quantitation) will be retested after a 20-25 year time lapse. Changes in individual bone mineral content and cortical volume during the intervening quarter century will be determined by radiographic densitometry using the Texas Woman's University method (with recently incorporated improved technology); direct radiographic scaling of bone morphology; and, terminally, by gamma ray absorptiometry using the Norland-Cameron method.

Bone changes during the time period will be compared with the 'normal' profile of bone development/regression currently being ascertained through our contractual work with the National Center for Health Statistics. This work encompasses bone mineral and cortical thickness measurements of 12,000 individuals who have been computer-selected by the Bureaus of Census to represent the United States population.

The specific aim of the proposed program is to determine if bone rarefaction with age is uniform and universal, or if nutritional, environmental/occupational, or pathologic factors are conducive to deviations from the normal profile which may result in the syndrome known as osteoporosis.

ABORTION--SUBSEQUENT REPRODUCTIVE FUNCTION/PREGNANCY
C.S. Chung, University of Hawaii System, Manoa Campus, School of Public Health, Dept. of Public Health Sciences, *Spalding Hall, Room 255, Honolulu, Hawaii* 96822
Quantify the effects of induced abortion on subsequent reproductive function by performing a classical cohort study of 16,500 women who collectively underwent 17,700 recorded abortions in the State of Hawaii between July, 1970, and July, 1974. Compare pregnancy outcome rates of pregnancies occurring to these women between January, 1971, and December, 1976, to rates of two control groups: the entire set of live births and fetal deaths for the period January, 1971, through December, 1976, minus those occurring to women in the 'recorded abortion' group; and births or fetal deaths occurring to women with no recorded abortion history matched to the 'recorded abortion' group by maternal age, racial background, residence (urban vs. rural), and birth order. Specifically, compare rates of fetal death, neonatal death, prematurity, ectopic pregnancy, and labor and delivery complications.

PHARMACOKINETICS & TERATOGENICITY OF ANTICONVULSANTS
R.E. Ramsay, University of Miami, School of Medicine, Dept. of Neurology, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152 (R01 HD 12740-02)
The objective of the proposed project is to study prospectively (1) the effects which pregnancy has on the epileptic patient and (2) the teratogenic effect of anticonvulsant drugs. Evidence to date indicates that pregnancy may alter the pharmacokinetics and metabolism of drugs. Alterations in drug dosages are definitely necessary to maintain seizure control during pregnancy. Seizures exacerbate in more than 50% of pregnant epileptics, even when drug dosages are appropriately changed. The frequency of this change has not been accurately documented and the etiology, which may be secondary to changing hormone levels, has not been clarified. Studies on teratogenesis of anticonvulsant drugs have con-

centrated on the changes in the children but have not examined the mothers during pregnancy to document their metabolic or drug status. In this project, we propose to examine both the mothers during pregnancy and their offspring. The children will be reexamined periodically for years. Major malformations occur in 6 to 8% of children born to mothers taking anticonvulsant drugs. Up to 30% may have dysmorphic features. Delayed maturation and development has also been reported to occur but the true incidence, severity and etiology has not been defined. In this study, we hope to elucidate some of these questions by monitoring the mothers during pregnancy and serially examining the children for neurological, developmental and morphologic abnormalities.

PATHOBIOLOGY OF AMENORRHEA/HYPERPROLACTINEMIA

B.M. Sherman, University of Iowa, School of Medicine, Dept. of Internal Medicine, *Jessup Hall, Iowa City, Iowa* 52240 (R01 HD 13136-01A1)

This proposal will use clinical, anatomic, endocrine, histopathologic and epidemiologic methods to gain information that will substantiate the hypothesis that potentially prolactin-secreting adenomas of the pituitary may exist in as many as 5% of women, that they may be a frequent cause of ovulatory dysfunction and infertility, and that their growth and clinical expression may be stimulated by estrogen use, usually in the form of oral contraceptives. An autopsy study will seek to determine the prevalence of prolactin-secreting adsnomas by immunocytochemical and electron-microscopic methods. A case-control study will ascertain whether oral contraceptive use and menstrual dysfunction are in fact more frequent in women with amenorrhea and hyperprolactinemia. A prospective study of oral contraceptive users will determine what proportion of women will develop frank hyperprolactinemia. The prolactin responses to a short course of estrogen administration will be assessed in women with ovulatory dysfunction and/or infertility who have basal serum prolactin concentrations in the high normal range and in a control group. This is an attempt to elaborate on the pathogenesis of pituitary adenomas and hyperprolactinemia and to design a method that will identify early those individuals who may harbor a nascent prolactin-secreting adenoma and who may be subject to estrogen-induced hyperprolactinemia.

EPIDEMIOLOGY OF EARLY REPRODUCTIVE LOSS

Z.A. Stein, Columbia University, College of Physicians & Surgeons, Dept. of Public Health, *630 W. 168th St., New York, New York* 10032 (R01 HD 12207-03)

Research questions of central interest are possible relations between the attributes and experiences of parents, and adverse reproductive outcomes. Attributes of parents include age, prior reproductive experiences, medical conditions including genetic disorders, demographic background; experiences include habits (cigarette smoking), home and job exposures to chemicals, therapeutic drugs, contraceptives. The adverse reproductive events are the event of spontaneous abortion estimated as an odds ratio, in a case-control study and the event at given stages of gestation; the karyotypic character of the abortus (euploid, trisomic, monosomic, triploid, tetraploid, translocation, mosaic, other); the morphology of the abortus beyond 28 weeks. There is also interest indifferences in sex ratio, and differential findings for male and female offspring.

Findings established by the study include: an excess risk for spontaneous abortion (and in particular, for euploid conceptions) among women who smoke during pregnancy, for those drinking in moderate amounts of alcohol during pregnancy, and for those whose conception occurred while using an intrauterine device; for women over 35 years; for women using heroin or methadone and women with a history of repeat abortions. The risk was not raised for those who had experienced a single previous induced abortion, nor for those who ingested saccharine.

CELL-MEDIATED IMMUNITY IN CONGENITAL CMV INFECTIONS

H.H. Balfour, University of Minnesota, Minneapolis Campus, School of Medicine, Dept. of Laboratory Medicine & Pathology/Pediatrics, *1305 Mayo, Minneapolis, Minnesota* 55455 (R01 HD 12342-02)

A CMV-specific cell-mediated immune defect has been found in 9 young children with congenital or neonatal CMV infections. To investigate the possibility that this defect could play a role in the pathogenesis of cytomegalic inclusion disease, we are performing an intensive epidemiologic, virologic and immunologic investigation of the role of CMV-specific cell-mediated immunity in mothers and their infants. Infants from newborn nurseries are being screened to detect active CMV infections. Those infected will have CMV-specific immune studies performed. Normal pregnant women are being studied to establish the effect of pregnancy on generalized and CMV-specific cell-mediated immunity. Infants with clinical manifestations of CMV will be followed for at least 3 years. At the present some of these infants are being enrolled on an open protocol to receive transfer factor prepared from adults shown to have cell-mediated immunity to CMV. In 2 such infants administration of transfer factor has been temporally related to cessation of viruria and acquisition of lymphocyte proliferative responses to CMV. To establish the normal kinetics of CMV humoral and cell-mediated immunity in normals, volunteers given live, attenuated CMV vaccine and adults with CMV mono are being followed.

3.0999,
PSYCHOSOCIAL AND PHYSICAL RESULTS OF TUBAL LIGATION

R.N. Shain, University of Texas, Health Science Center at San Antonio, Medical School, Dept. of Obstetrics & Gynecology, *7703 Floyd Curl Dr., San Antonio, Texas* 78284 (R01 HD 13459-01A1)

The objectives of the proposed study are to 1) determine the type and extent of long-term psychosocial and physical consequences which can be directly or indirectly attributed to tubal sterilization, 2) determine the conditions with respect to the (a) surgery itself (indications for, type and timing) (b) factors internal to the woman herself and (c) factors in the woman's personal situation which minimize and maximize the occurrence of positive outcomes as well as problems, and 3) develop an instrument which would help physicians select individuals with whom intervention with additional counseling and preparation is warranted.

In order to satisfy these objectives, a well-controlled prospective study of 250 randomly selected tubal ligation (postpartum and interval) patients and 2 control groups (250 women who have completed childbearing but do not anticipate a tubal ligation or a vasectomy for their mates, and are relying on other contraceptive methods, and 250 wives of vasectomy patients) is proposed. Age, parity, and contraceptive method used prior to sterilization will be the major control variables. Where initial analysis indicates that these variables are related to outcomes, post-hoc matching with respect to that variable will be introduced.

Measures of all relevant psychosocial and physical variables with respect to both the study and control groups will be determined prior to the surgery (at a randomly assigned time for temporary method users) so that changes can be documented at one and two years following the initial interview.

All data involving demographic, psychosocial, and physical variables will be collected through the initial and followup interview schedules, routine physical examination, and completion of the Physical Symptoms Checklist.

Data analysis will focus upon characterizing the physical, demographic and psychosocial features of both study and control groups, determining which of the various variables predict consequences of tubal sterilization during the first two years following surgery, and comparing the study and control groups on their initial features and responses toward sterilization.

3.1000,
RISK FACTORS FOR PREGNANCY COMPLICATIONS IN SMOKERS

M.B. Meyer, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 HD 13583-02)

The risks of early and late bleeding, placenta previa, abruptio placentae, and premature and prolonged rupture of membranes increase with increasing levels of maternal smoking during pregnancy. However, the degree of risk appears to vary depending on other maternal factors. The objectives of this study are: 1) to identify women in terms of age-parity, socioeconomic status, height, weight, weight gain, hemoglobin level, past obstetric and medical history, use of medical services, and other factors who will be at highest risk for these complications if they smoke; 2) to trace the progression of these complications prospectively to preterm or term delivery and to perinatal death or survival, weighing the relative importance of maternal smoking and of other risk factors in the process; 3) to serve as a model for future prospective studies by identifying mothers at maximum risk of complications and by determining an optimum comparison group.

Data from the Ontario Perinatal Mortality Study are now being analyzed to fulfill these objectives. Preliminary findings indicate the relative importance of maternal smoking and other antecedent factors to a) the occurrence of selected pregnancy complications and b) the incidence of adverse pregnancy outcomes with and without these complications. The current application is for support for a similar analysis of data from the Jerusalem Perinatal Study, which have been made available to us since the original application. Advantages of using a second data set are that the consistency of results in a different population can be tested; Jerusalem data are more recent, and some complications of interest were more completely ascertained in Jerusalem. Data from both studies will be used a) to calculate sample sizes needed in prospective studies of pregnancy complications and b) to produce a nomogram to assess the risk of pregnancy complications and the risk of adverse pregnancy outcomes for women with different profiles, and to measure the impact of smoking on these risks.

GROUP B STREPTOCOCCAL INFECTIONS

H.C. Dillon, University of Alabama in Birmingham, School of Medicine, Dept. of Pediatrics/Microbiology, *1919 7th Ave. S., Birmingham, Alabama* 35233 (R01 HD 13920-01)

The natural history of group B streptococcal (GBS) infections is being investigated. Longitudinal, prospective clinical, epidemiological and serological studies are concentrated in the area of puerperal and perinatal infections. Maternal GBS carrier/infection rates are determined during pregnancy and at delivery. GBS acquisitions in prospectively studied newborns are defined according to culture sites, and the degree of exposure to GBS at or around time of birth is correlated with risk of disease. The spectrum of disease in infancy is defined and attack rates of early and late sepsis are determined. Maternal factors possibly predisposing to GBS infection are evaluated. The role of GBS in UTI in women with complicated pregnancies is being studied in separate but related investigation. Studies of host defense include assays for type-specific Ab in parturients and offspring and the relation between Ab and disease incidence. The role of homologous and heterologous carriage in the evolution of antibody is being explored. An ELISA method has been devised for seroepidemiological study. Protective Ab assays include the chick embryo and mouse protection models and indirect bactericidal test for opsonic Ab. Long-term

trends in maternal carriage/infection and neonatal disease caused by GBS will be determined in the course of this investigation in anticipation of the possibility for implementing and evaluating prophylactic or preventive measures.

3.1002,
ANALGESIA AND ANESTHESIA IN LABOR AND DELIVERY

B.J. van den Berg, University of California, Berkeley Campus, School of Public Health, Dept. of Biostatistics, *Berkeley, California* 94720 (R01 HD 14213-02)

This project is based on prospective longitudinal data assembled in the Child Health and Development Studies, starting with observations of 20,000 pregnant women and continuing with follow-up studies of the children born to these women.

The families were members of Kaiser Foundation Health plan in the Oakland area of California. The focus of this research project is on the evaluation of association of drugs, adminstered for analgesia during labor or for anesthesia during delivery, to health and development of the child at birth, as well as at the ages of 5 years and 10 years.

The data on the well-being of the children at 5 years and 10 years were obtained during developmental examinations of subcohorts of the basic population.

Though it is known that these drugs pass the placenta to reach the fetal circulation, and sometimes have transient undesirable effects on the newborn, associations between these drugs and later development of children have hardly been studied. Our longitudinal observations will be used to approach this problem.

3.1003,
MORTALITY LEVELS AND DIFFERENTIALS IN THE U.S., 1900

S.H. Preston, University of Pennsylvania, School of Arts & Sciences, Dept. of Sociology, *34th & Spruce Sts., Philadelphia, Pennsylvania* 19104 (R01 HD 14359-01)

The project is designed to provide more reliable estimates of mortality than are currently available for the American population at the turn of the century. At this time there was a rich diversity of social conditions deriving from recent industrialization and rapid immigration. A 1 in 753 sample of households from the 1900 U.S. Census of Population will be the principal data source. Census questions on children ever born and children surviving will be converted into estimate of child mortality for the whole population and for significant social groups. Particularly valuable will be estimates for the rural population and for blacks, groups that were severely underrepresented in the Death Registration Area in 1900. Multivariate techniques will be developed to permit examination of the independent effect of specific factors on mortality. Inferences regarding adult mortality conditions among various groups can be made by reference to a model life table system that appears broadly applicable to American experience at this time.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Child Health & Human Development $84,366

3.1004,
PARENTAL OCCUPATION AND PREGNANCY OUTCOME

B.J. van den Berg, University of California, Berkeley Campus, School of Public Health, Dept. of Biomedical & Environmental Health Sciences, *Berkeley, California* 94720 (R01 HD 14522-01)

This research project will address the following questions: (1) Does employment during pregnancy have measurable (unfavorable) effects on the course of pregnancy and/or health and development of fetus and infant? (2) Can specific types of occupation of either father or mother be identified that have measurable effects on the course of pregnancy or on the health and development of the offspring?

The data for this research are assembled in the Child Health and Development Studies, including information on 15,000 families. The procedures will be to investigate relationships of a variety of parental occupations to the course of pregnancy and pregnancy complications; to the health of the newborn, as well as to subsequent growth and development of the child. The data are large enough to control for confounding variables.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Child Health & Human Development $60,134

3.1005,
ORGANIZATION OF SLEEP STATES AND RISK FOR SIDS

R.M. Harper, University of California, Los Angeles Campus, School of Medicine, Dept. of Anatomy, *2025 Zonal Ave., Los Angeles, California* 90024 (R01 HD 14608-01)

This project will examine the temporal patterning of autonomic, central nervous system and somatic activity during sleep-waking states in normal infants and infants at risk for the Sudden infant Death Syndrome (SIDS). The objective is to determine whether sleep disturbances, previously noted in infants at risk for SIDS, results from a failure to arouse from apneic and other transient events during sleep. Physiological activity during sleep will be examined by measuring EEG, somatic activity, and cardiac rate variability before and after apnea and transient events of sleep, and during transition periods between states. These studies will be carried out on data already collected from normal infants and siblings of SIDS victims over the first 6 months of life. The integration of sleep states will be studied by examination of coupling between sequencing of particular states and temporal patterning of physiological activity. The presence of fast ultradian periodicities will be studied in each age group.

3.1006,
SOCIOECONOMIC EFFECTS ON CHILD MORTALITY IN THE U.S.

R.D. Mare, University of Wisconsin, Madison Campus, School of Letters & Science, Dept. of Sociology, *500 Lincoln Dr., Madison, Wisconsin* 53706 (R01 HD 14690-01)

The proposed research assesses the effects of socioeconomic conditions on the mortality of chilren aged one through twenty in the United States. Except for aggregate analyses, research on socioeconomic mortality differentials has been confined to adults or infants. This research investigates the extent, pattern, trend, and causes of socioeconomic child mortality differentials and develops methods for using limited data to infer socioeconomic effects. The analysis is based on mothers' reports of the survival status of their children contained in the June 1975 and 1980 Current Population Surveys (CPS) and on indirect estimates from the 1960 and 1979 Census Public Use Samples and the 1975 and 1980 June CPSs. The goals of the research are to estimate child mortality rates specific to socioeconomic characteristics of parents and families through several procedures; to perform multivariate analysis of June CPS data to assess the independent effects of mother's schooling, family income, father's schooling, father's occupation, family size and structure, mother's age, race, sex, and age on child mortality; to develop indirect estimates of child mortality differentials from the 1960, 1979, 1975, and 1980 data to assess changes in socioeconomic effects; to develop and test a hypothesis that socioeconomic child mortality differentials are strongest in populations in which accident mortality constitutes the largest proportion of deaths (that is, among boys, blacks, and teenagers, and for the most recent period); to use data on the mortality of siblings (from the June CPSs) to statistically control family-related sources of population heterogeneity in making differential mortality comparisons; and to develop modified Brass and intercensal survival methods to estimate socioeconomic child mortality differentials from U.S census data.

3.1007,
FETAL DEATH IN LABOR - EPIDEMIOLOGY AND PREVENTABILITY

N.S. Paneth, Columbia University, College of Physicians & Surgeons, Dept. of Pediatrics/Public Health, *630 W. 168th St., New York, New York* 10032 (R01 HD 14807-01)

Using vital records of the City of New York, we will examine the epidemiology of intrapartum fetal death (IFD) in a total population. The variations of this component of perinatal mortality in time, place, and season, and in relation to social, demographic and maternal risk factors will be studied. We will compare the distribution of such variables among cases of IFD, to their distribution among the other components of perinatal mortality: late antepartum fetal death and early neonatal mortality.

Completion of the descriptive and comparative epidemiology will be followed by analysis of the relationship of obstetric care to IFD rates, the latter standardized for confounding factors. This study builds on our present study of hospital care and neonatal mortality and makes use of our knowledge of equipment, procedures, and staffing in each of New York City's maternity services.

The analysis will be performed on several levels: 1) A cross-sectional comparison of IFD rates and maternity service quality scores. 2) A comparison of IFD rates and rates of labor surveillance and intervention by hospital. 3. An analysis of the secular trend of IFD rates in relation to secular trends in rates of obstetric intervention.

By the end of the study we expect to have a firm understanding of the descriptive and comparative epidemiology of IFD in our population. We further expect to know how IFD rates vary in relation to quality of maternal care, intensity of labor surveillance and frequency of obstetric intervention.

3.1008,
DEVELOPMENTAL DYSLEXIA - CROSS-NATIONAL COMPARISONS

S.D. Lindgren, University of Iowa, School of Medicine, Dept. of Neurology, *Oakdale, Iowa* 52319 (R01 HD 15026-01)

This study is the second phase of a cross-national investigation of developmental dyslexia in Italy and the United States. Assessing children in differing linguistic environments provides an opportunity to evaluate the degree to which the phonetic regularity of a language influences the prevalence and types of dyslexia. Children in a linguistic environment where dyslexia is reportedly rare and where the language shows relatively consistent grapheme-phoneme correspondence (Italy) will be compared to children in a setting where dyslexia is common and where the language is comparatively irregular (the U.S.). This will permit analysis of the interaction between phonetic-linguistic factors and individual patterns of cognitive ability. Cognitive patterns will be examined by analyzing the children's performance on a battery of neuropsychological tests assessing both auditory-verbal and visual-spatial abilities. The performances of dyslexic children will be compared to the performances of children with adequate reading skills in order to determine the proportion of dyslexics whose reading disability is related to specific deficits in verbal or spatial processing. The study will attempt to discover whether the orthographic regularity of the Italian language reduces the prevalence of dyslexia, modifies the neuropsychological characteristics of the disorder, creates a dissociation between reading comprehension and decoding, and produces shift in the type of reading errors, when compared to American children. Understanding the effects of linguistic factors on the prevalence and pattern of reading disabilities should have direct impact on clarifying the etiology of dyslexia and should have important implications for developing strategies for remediation.

3.1010,

THE GEOGRAPHIC VARIATION OF FETAL AND INFANT MORTALITY AND LOW BIRTH WEIGHT IN THE UNITED STATES, 1969-1974

C.A. Keller, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Child Health & Human Development, Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-HD-00305-03 EB)

The assembly of a large number of variables, including pregnancy outcome, has provided data on the marked variability in infant and fetal mortality among different populations in the U.S. The correlation of adverse pregnancy outcome rates with environmental variables will make it possible to assess the relative importance of the various factors associated with these rates in a large population. These data will also provide a basis for the assessment of changes in infant and fetal mortality which may be occurring in some populations.

3.1011,

THE SEASONALITY OF INFANT MORTALITY FROM LINKED BIRTH-DEATH RECORDS IN NORTH CAROLINA, 1967-1973

R.P. Nugent, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Child Health & Human Development, Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-HD-00306-03 EB)

The observed seasonality of neonatal deaths in the U.S. has implications as to the role of environmental agents, e.g., infectious organisms, during pregnancy in influencing pregnancy outcomes. Since seasonality of conceptions may generate seasonality of neonatal death rates, linked birth-death records from North Carolina and Minnesota are being utilized to examine this relationship so that seasonality of death rates can be assessed independently of any seasonal variation in conceptions.

STUDY OF LINKED INFORMATION OF INFANT DEATH CERTIFICATES AND LIVE BIRTH CERTIFICATES FOR SELECTED U.S. STATES

H. Hoffman, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Child Health & Human Development, Biometry Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-HD-00802-05)

The objective is to assemble a multi-state data file of infant deaths in which prior linkage with birth certificate information has been performed. The studies to be done on the data set include associations between infant (and fetal) mortality with the standard information on birth certificates (e.g. birth weight, gestational age, maternal age and race, parity, etc). These studies will be compared with similar studies on a 1950 and 1960 cohort of U.S. births. Additional comparisons will be linked data from Canada (1971), Great Britain (1970) and Norway (1976-1973).

LONG-TERM EFFECTS OF DIETHYLSTILBESTROL DURING PREGNANCY

A.L. Herbst, University of Chicago, Pritzker School of Medicine, Dept. of Obstetrics & Gynecology, *5801 S. Ellis Ave., Chicago, Illinois* 60637

OBJECTIVE: Continue examinations of both male and female offspring of women given diethylstilbestrol (DES) or placebos during pregnancies in 1951 and 1952 in a double-blind study. The aim is to assess the possible long-term effects of DES on sexual development, fertility, complications in pregnancy, and the development of precancerous lesions or carcinoma. It is also proposed to continue follow-up of the mothers who were administered DES or placebos during pregnancies. They should be contacted at least once during the three-year period for telephone interview, with documentation of pathology by hospital records.

PERINATAL INFECTIONS, IMMUNITY AND MALDEVELOPMENT

C.A. Alford, University of Alabama in Birmingham, School of Medicine, Dept. of Pediatrics, *1919 7th Ave. S., Birmingham, Alabama* 35233 (P01 HD 10699-04)

The major objective of the program project is to study the natural history of perinatal cytomegalovirus (CMV) infections in mothers, infants and children by large scale, prospective and longitudinal investigations. The CMV studies include in the mothers: 1) the role of recurrent versus primary infection in intrauterine and intrapartal transmission, 2) mechanisms of fetal transmission with recurrent maternal infection and, 3) effect of pregnancy hormones on growth of CMV. In infants and children they include studies on: 1) long-term developmental outcome, 2) assessment of immunologic assays for detection of silent infection in the newborn, 3) pathogenetic studies of severe disease and, 4) nature of immune complex formation in congenital CMV. In addition, longitudinal studies of the humoral and cellular immune response in the maternal, congenital and natal infections are to be determined and related to virologic and clinical parameters over time. Human strains of virus are to be also genetically analyzed and related to the disease state in man to search for microbial virulence factors.

DETERMINANTS OF URBAN MORTALITY - LATE 19TH CENTURY PHILADELPHIA

G.A. Condran, University of Pennsylvania, School of Public & Urban Policy, Dept. of Demography, *203 Logan Hall, Philadelphia, Pennsylvania* 19104 (R01 HD 12413-03)

The proposed research focuses on the determinants of the urban mortality transition in the late nineteenth and early twentieth centuries. Although scholars agree that major advances in diet and nutrition, sanitation and environment, and medicine and medical care all contributed to a decline in mortality, few specifics are known about their separate effects. We propose to examine the relative contributions of these various factors through an intensive case study of the shifts in mortality in the city of Philadelphia from 1880 to 1930. Using both published aggregate mortality statistics covering the entire time period, and data for individual decedents from 1880, 1900, and 1930, we will study the changes in the age and cause-of-death structure of mortality during the transition.

Our specific aims are threefold. First, to isolate the shifts in cause- and age-specific mortality rates which account for the change in the overall mortality levels in Philadelphia. Second, to examine mortality differentials by race and ethnicity, by geographic area, and by socioeconomic status for the years 1900 and 1930. These efforts will build upon our ongoing analysis of the same differentials in 1880. We will establish whether the mortality decline occurred differentially across population subgroups and across spatial units within the city. Third, to determine the changes in mortality from specific causes in relation to the factors affecting mortality levels. The relative contributions of changes in food and housing, public health measures, and improvements in medical practice along with changes in the population composition and the general environment will be examined for the city as a whole and for small areal units within the city. This analysis will use individual death records in conjunction with data from a combination of sources including vital statistics reports, board of health reports, manufacturing and population censuses, and hospital records.

PREGNANCY OUTCOMES IN HUMAN POPULATIONS

M.P. Mi, University of Hawaii System, Manoa Campus, John A. Burns School of Medicine, Dept. of Genetics, *2444 Dole St., Pacific Biomedical Res. Ctr., Honolulu, Hawaii* 96822 (R01 HD 12142-03)

The project is to utilize two computerized population data bases for genetic and epidemiologic studies of pregnancy outcome. These unique resources, one in Hawaii and the other in British Columbia, have been similarly developed from routinely produced vital and ill-health records. These include records of all fetal, infants, and childhood deaths and livebirths recorded in each population over a long period of time. In addition, records from a health surveillance registry and selected childhood hospitalization are also available in one of the populations. By means of computerized linkages, these records have been assembled into individual and family health histories on a population basis. It is planned to analyze the etiological components of empiric risks of fetal wastage, perinatal and infant deaths, and congenital malformations at a population level. It is specially designed to study familial recurrence risks of pregnancy wastage and to develop means for identifying high-risk families.

3.1033,
DETERMINANTS OF CHILD MORTALITY

T.P. Schultz, Yale University, Graduate School, Dept. of Economics, *206 Elm, New Haven, Connecticut* 06520 (R01 HD 12172-03)

The proposed research is concerned with the development of approaches to evaluating the impact of family planning and medical inputs on infant health. The major objective of the research is the measurement of the joint effects of family behavior, environmental factors and health program inputs, such as the use and availability of medical inputs, female labor-force participation, family size, cigarette smoking and pollutants, on infant mortality rates and birthweight. Statistical procedures will be used which take into account the potentially simultaneous nature of related household decisions and child health outcomes. Data on socioeconomic characteristics of family members, behavior, and measures of child health from national surveys will be analyzed in conjunction with aggregate data on the price and availability of various medical services in the region in which the household resides. The areal information on prices and conditions confronting the household may be assumed exogenous to its behavior and health outcomes. Linking this areal data to household records permits, therefore, one to identify how a variety of program activities and prices affect birthweight and child survival both directly and indirectly by influencing related household behavior. Within the limitations of existing data files and the many and imperfectly integrated hypotheses concerning the causes of child health status, the proposed research aims to test certain of these hypotheses in a common statistical and economic framework.

UREAPLASMA UREALYTICUM--THREAT TO PERINATAL SURVIVAL

R.B. Kundsin, Harvard University, Boston Campus, School of Medicine, Dept. of Microbiology & Molecular Genetics, *25 Shattuck St., Boston, Massachusetts* 02115 (R01 HD 10984-03)

This study proposes to prospectively investigate the presence of Ureaplasma urealyticum (T-mycoplasmas) in the lungs and fetal membranes of infants dying during the perinatal period. Cultures will also be done for Mycoplasma hominis, Chlamydia trachomatis, cytomegalovirus, aerobic and anaerobic bacteria, including Group B streptococci. The results will be correlated with perinatal death. The two most common disorders in which ureaplasmas have been implicated in the perinatal period are congenital pneumonia and chorioamnionitis. Chlamydia trachomatis and cytomegalovirus have been implicated in infants with interstitial pneumonia. Stillborn and liveborn deaths from 20 weeks' gestation through 28 postnatal days will be studied. It is anticipated that 100 such deaths will occur per year for a total of 300 in the three year period covered by this proposal. The results of cultures will be related to clinical and pathologic findings of the infant and with the histology of the placenta. As controls, 100 placentas of normal, full-term infants will be similarly cultured; 100 additional placentas of infants admitted to the intensive care unit and surviving will also be cultured. The microorganisms studied are sexually transmitted and genitourinary tract infections can occur prior to or during pregnancy. Fetal infection with these microorganisms is a logical sequel. The joint expertise of a pathologist, neonatologist, and microbiologists will all focus on the problem of perinatal mortality. Such a multidisciplinary approach should define the role of the microorganisms studied on poor pregnancy outcome.

BIBLIOGRAPHIC REFERENCES: Kundsin, R.B., Parreno, A., and Poulin, S.: Significance of appropriate techniques and media for the isolation and identification of Ureaplasma urealyticum from clinical specimens. J. Clin. Microbiol. 8(4):445-453, 1978.

3.1035,
PREGNANCY AND DES ASSOCIATED UPPER GENITAL ANOMALIES

R.H. Kaufman, Baylor College of Medicine, School of Medicine, Dept. of Obstetrics & Gynecology, *1200 Moursund Ave., Houston, Texas* 77025 (R01 HD 10989-04)

The investigators intend to continue their studies of the prevalence of upper reproductive tract anomalies in a patient population exposed in utero to diethylstilbestrol. These patients are adult females of child bearing age who were exposed in utero to diethylstilbestrol.

A relationship between upper genital tract abnormalities noted and pregnancy outcome will be studied. This will be accomplished by conducting a retrospective and prospective correlation of each patient's pregnancy outcome with the types of anomalies found.

The detection of the upper genital tract anomalies will be carried out by the use of hysterosalpingography.

The patients to be studied are presently enrolled in another federally funded project and will be contacted and recruited into the current study. Currently, over three hundred DES exposed women who have had hysterosalpingograms are being followed. It is proposed to increase the number of women studied by HSG to at least seven hundred and to further relate the pregnancy outcomes of these women to the changes noted in the x-ray studies.

3.1036,
PHYSIOLOGIC AND DEVELOPMENTAL MECHANISMS IN DIABETES

R.E. Greenberg, University of New Mexico, School of Medicine, Dept. of Pediatrics, *University Hill N.E., Albuquerque, New Mexico* 87131 (P50 HD 11327-04)

The general objective of this proposal is to develop a center of the study of the relationship between aberrant carbohydrate metabolism and developmental events in animals, established disease patterns in humans, its effect on the offspring and the mechanisms leading to the diabetic state in both animals and humans. It is anticipated that this effort will provide a more rational therapy for diabetic patients.

The specific objectives are to a) clarify the relationship between diabetes in women and the occurrence of congenital abnormalities in their offspring, b) determine the mechanisms operative in regulation of carbohydrate metabolism during immediate extrauterine adaptation, c) study the factors modulating insulin receptor number and/or affinity during development, d) study the mechanisms leading to hyperinsulinemia and its effects on hepatic hormone clearance, hepatic ketogenesis and glycogenolysis in the genetically obese rodent, e) develop an external programmable microelectronic control system for insulin administration in the control of diabetes mellitus in humans after appropriate observations in diabetic dogs, with an implantable pump reservoir system exploring the feasibility of intraperitoneal versus intravenous insulin therapy, and f) clarify the interrelationships between insulin binding, internalization and degradation and the factors that regulate the metabolic disposition of insulin.

3.1037,
DIFFERENTIAL FERTILITY & MORTALITY

R.C. Avery, Cornell University, Ithaca Campus, Center for International Studies, International Population Program, *Ithaca, New York* 14850 (R01 HD 11348-03)

The project studies comparative differential fertility and child mortality in four Central American nations (Costa Rica, El Salvador, Guatemala, and Honduras). Attention is focused on the period surrounding and prior to the 1970-round censuses, and particular interest is paid to the factors operating at the environmental level (involving the structure of the community, government and private services, housing, and household characteristics) and at the individual level. Two main sources of data are used: (a) large microsamples of the 1970-round censuses; and (b) data on small areal units constructed from various sources.

3.1038,
PREGNANCY COMPLICATIONS AFTER INDUCED ABORTION

M.B. Bracken, Yale University, School of Medicine, Dept. of Epidemiology & Public Health/Obstetrics & Gynecol, *333 Cedar St., New Haven, Connecticut* 06510 (R01 HD 11357-02)

This prospective cohort study will provide estimates of the relative and attributable risks of different induced abortion experiences and procedures for a number of complications of subsequent pregnancies, labor, deliveries and newborns.

All women (estimated n equals 8,000) who have made a first prenatal visit to physicians, health plans and clinics, and who anticipate delivery at Yale-New Haven Hospital, will be invited to participate in the study. To ascertain information about abortion experiences and other risk factors patients will be interviewed, with their physicians's consent, using a standardized questionnaire given by trained interviewers. Supplemental information will be obtained from physicians and clinics where abortion was obtained. Information about pregnancy outcomes will be obtained by surveying all deliveries at the hospital and linking these to respondents who have been interviewed. Obstetricians and patients may be recontacted if necessary.

In the analysis complications of pregnancy, labor, delivery and in newborns will be compared in women exposed and not exposed to prior abortion. Experience of abortion will include: number and sequence of abortions, technique used and gestation at abortion. Possible confounding factors will be accounted for such as: maternal age, pregnancy history, smoking history, history of venereal infections, interpregnancy intervals and contraceptive use. A multivariate analysis using log liner models will be used which can identify sub-groups of women who have unusually high or low risk of developing complications if exposed to induced abortion.

3.1039,
CONTRIBUTION OF IRON DEFICIENCY TO MENTAL RETARDATION

J.C. Martin, University of Washington, School of Medicine, Dept. of Psychiatry & Behavioral Sciences, *A-300 Health Sciences Ctr., SC-64, Seattle, Washington* 98195 (P01 HD 11680-02)

The most widespread nutritional deficiency in the country today is iron, particularly in pregnant women and children in different socio-economic strata. A variety of metabolic disturbances and physiological and developmental changes appear to be concommitants of iron deficiency during pregnancy, including low birth weights, increased still-birth rate, elevation of toxemia, and possible increases in fetal anomalies. Some studies suggest that iron deficient children have lower I.Q.'s and poorer academic performance. In addition they are described as inattentive, hyperactive, perseverative, and poorly integrated, all

behaviors which would retard their learning and performance.

Recent evidence for central nervous system disorders from iron deficiency which involve the serotonin pathway and by implication mental function, led to the enclosed program project. This is a collaboration between the departments of Psychiatry & Behavioral Sciences, Pediatrics, Laboratory Medicine, Medicine, Biostatistics and the Child Development Mental Retardation Center.

Th metabolic and behavior concommitants of iron deficiency will be examined both longitudinally in the infants of iron deficient women, and cross-sectionally in iron deficient children. In addition an animal model will be utilized in parallel studies.

Eight senior investigators are submitting four related research projects to be performed collaboratively.

3.1040,
UNSUSPECTED INFECTION AND PERINATAL MORBIDITY

E.H. Kass, Harvard University, Boston Campus, Peter Bent Brigham Hospital, Dept. of Medicine, *721 Huntington Ave., Boston, Massachusetts* 02115 (P01 HD 11924-03)

The role of unsuspected maternal infection in the pathogenesis of perinatal morbidity has assumed increasing importance as newer knowledge has accumulated. Classically, symptomatic infections have always been recognized as being responsible for much perinatal morbidity. Studies of asymptomatic bacteriuria have demonstrated a relation between unsuspected infection and perinatal morbidity. Recent observations in this laboratory now indicate a relation between genital mycoplasmas and such morbidity. It is proposed to explore further this relation by the the following approaches: 1) to continue ongoing studies of the effect of antimicrobial agents on the outcome of pregnancy, in terms of low birth weight, postpartum fever and associated morbidity; 2) to examine further the relation between changes in antibody titer to genital mycoplasmas and the outcome of pregnancy, with particular emphasis on the role of Ureaplasma urealyticum; 3) to study further the role of bacteremia due to genital mycoplasmas, and particularly that due to M. hominis, occurring during the second stage of labor; 4) To determine whether any specific serotype of M. hominis or of U. urealyticum is associated with morbidity; 5) to determine if genital mycoplasmas play similar role in pregnancies of women from more affluent social classes that they do in those of the social classes that have thus far been studied; 6) to determine interactive affect between genital mycoplasmas and other microflora of the genital tract, including Chlamydia trachomatis, trichomonas, group B Streptococcus, Haemophilus vaginale, Herpes hominis, selected anaerobes, and related microflora; 7) to investigate further the possible effect of U. urealyticum as a suppressant to antibody formation; 8) to continue analyses of the antigenic components of the membrane of different strains of genital mycoplasmas, in order to develop better serologic tests, and in order to isolate in purified form the major antigenic components.

3.1041,
CYTOMEGALOVIRUS - TRANSMISSION TO NEWBORNS BY BLOOD

A.S. Yeager, Stanford University, School of Medicine, Dept. of Pediatrics, *300 Pasteur Dr., Stanford, California* 94305 (R01 HD 09872-05)

The purpose of the investigation is to determine whether the risk of transfusion-acquired cytomegalovirus (CMV) infections in premature infants can be decreased by the use of donors who have no measurable antibody to CMV and to evaluate the most practical assay for use by a blood bank. Host factors which influence the severity of the disease in the baby are being evaluated.

Severe infections have been identified in infants of seronegative mothers. Surviving infected infants are being studied in comparison with controls for the possibility that prenatally acquired CMV infections result in long term sequelae in premature infants. Tests of vision, hearing and intellectual function are being performed at 1, 2 and 3 years of age. Current studies are aimed at identifying the reasons for the failure of infected infants to respond to CMV antigen in the lymphocyte transformation assay. The transmission of CMV from infected baby to seronegative household contacts is being investigated in an effort to evaluate the risk of transmission from infected infants to seronegative mothers during a subsequent pregnancy.

CLINICAL CORRELATIONS TO VITAMIN D STATUS IN INFANTS

L.S. Hillman, Washington University, School of Medicine, Dept. of Pediatrics, *660 S. Euclid Ave., St. Louis, Missouri* 63110 (R01 HD 09998-04A1)

The objectives of the grant are to define the short and long term effects of 25-hydroxy-vitamin D (25-OHD) deficiency, specifically focusing on 6 defined infant problems and to begin to define rational prophylaxis. To date, 80 premature and 35 SGA infants have been prospectively followed and 6 infants with late neonatal hypocalcemia and 30 SIDS infants have been studied. The study has defined 1) a high incidence of early neonatal hypocalcemia without significant correlation to low 25-OHD, 2) no evidence for 25-OHD deficiency in late neonatal hypocalcemia but evidence for low PTH, 3) a strong association between 25-OHD deficiency and osteopenia, fractures, and rickets plus hypocalcemia (P less than .01) and hypophosphatemia (P less than .01) at 3 months of age, 4) a significant (P less than .02) correlation between 3 month 25-OHD and 1 year height percentile correlated for gestation with a fourth of infants less than third percentile for height at 1 year, 5) a 25 percent incidence of abnormal upper incisors plus delayed eruption of teeth corrected for gestational age, 6) no evidence for a deficiency of serum 25-OHD in SIDS; however, confirmation of costochondral junction abnormalities. This grant will a) continue long term follow-up of infants currently enrolled in the study; b) begin to evaluate short and long term effectiveness of three alternative treatment trials; 1) higher dose vitamin D, 2) 25-hydroxycholecalciferal supplementation, and 3) calcium supplementation; c) further explore the roles of elevations of calcitonin and depression of PTH in early and late neonatal hypocalcemia; d) use tissue measurements to define whether total body deficiencies of calcium, magnesium, copper, and zinc do exist in premature infants and SIDS; e) further define histologically the normal process of in utero bone formation and define how premature infants with osteopenia and SIDS infants differ from that process.

SEX CHROMOSOMAL ABNORMALITIES - A PROSPECTIVE STUDY

A. Robinson, National Jewish Hospital & Research Center, *3800 E. Colfax Ave., Denver, Colorado* 80206 (R01 HD 10032-06)

The purpose of this research is to continue our study of a group of children with abnormalities of the sex chromosomes who were identified in a cytogenetic survey of 40,000 consecutive births from 1964-1974. Our long-term objective is to define the ultimate prognosis for each of these conditions--47,XXX; 47,XXY; 47,XYY; 45,X and mosaicisms of these. Data from biased samples of children and adults with these karyotypes indicate that they are at an increased risk for intellectual, emotional, social or physical problems in later life. The data from this 'Family Development Study' are being analyzed by comparisons between subgroups and by using chromosomally normal siblings as controls. We have identified delayed language development as an important problem in many of the propositi, and are conducting an in-depth study in this area.

The chief investigator and his associates have been receiving inquiries from all over the world as to the prognosis of fetuses identified in utero as having these karyotypes, thus stressing one significant result of these continuing studies.

ACUTE RESPIRATORY ILLNESSES IN SURVIVORS OF INFANT RDS

M.G. Myers, University of Iowa, School of Medicine, Dept. of Pediatrics, *Jessup Hall, Iowa City, Iowa* 52240 (R01 HD 10598-03)

Infant survivors of idiopathic respiratory distress syndrome (RDS) develop pulmonary residua which are believed to predispose these infants to more frequent and/or more severe respiratory infections. To assess this aspect of the long-term morbidity of RDS, we are systematically and prospectively evaluating the frequency, severity, and etiologies of acute respiratory illnesses in survivors of RDS, and preterm infants who did not have RDS compared to normal infants matched for sex, race, season of birth and presence of pre-adolescent children in the household.

DEVELOPMENTAL EFFECTS OF LOW LEVEL LEAD EXPOSURE

H.L. Needleman, Childrens Hospital Medical Center, *300 Longwood Ave., Boston, Massachusetts* 02115 (P01 HD 08945-04A1)

This Program Project Grant proposes to extend our studies of low level lead exposure in children and experimental animals to address the following questions: 1) Does prenatal exposure to lead affect outcome at birth and later in life? 2) Does lead exposure have long delayed effects related to aging or late neurologic disease? 3) Does chelation prevent demonstrated changes in synaptic maturity and dendritic complexity?

Epidemiologic studies of gravid women and their offspring in which lead is the risk factor will conducted, treating birth outcome and later development as outcome variables.

Animal models of controlled lead exposure will be employed to test the same hypotheses under experimental conditions. Animals will be given controlled amounts of lead at varied periods of gestation, and offspring studied for ultrastructural changes in brain, distribution of lead by radiosotopes, and behavioral change by quantitative techniques. The effects of chelation on outcome will also be studied.

DIPLOCOCCUS PNEUMONIAE - INFECTION AND IMMUNITY

H.C. Dillon, University of Alabama in Birmingham, School of Medicine, Dept. of Pediatrics, *1919 7th Ave. S., Birmingham, Alabama* 35233 (R01 HD 09732-05)

The natural history of Str. pneumoniae infections is being studied in a group of infants now 3-4 years of age, who have been followed since birth. The relation between pneumococcal carriage, infection and immunity is being determined in prospective fashion. Pneumococci are serotyped with Danish reference antisera. Antibody is determined in this laboratory by NBT assay and by a newly developed ELISA method. Collaborative arrangements with Dr. Gerald Schiffman provide for antibody assay by the RIA technique. In addition to patients prospectively investigated, seroepidemiologic studies are being performed, utilizing sera for children and adolescents stored from prior investigations. Included in the latter are sera from patients with well-defined pneumococcal infections. including otitis media and bacteremia. Comparative epidemiology of pneumococcal infections in children and adults is investigated by examining collections of clinically relevant pneumococci from pediatric and adult infectious disease services. Host age range, clinical syndrome, serotype causing disease, serological response to infections and seasonal trends of pneumococcal disease are being determined.

MENTAL RETARDATION RESEARCH CENTER

N.A. Buchwald, University of California, Los Angeles Campus, Neuropsychiatric Inst., *760 Westwood Plaza, Los Angeles, California* 90024 (P30 HD 04612-12)

This proposal provides central support for Research in Mental Retardation at UCLA. The Mental Retardation Research Center at UCLA is a multi-funded, interdisciplinary research and teaching program which has the following objectives: 1. Research into problems of mental retardation and related aspects of human development. 2. Research training, at the pre- and post-doctoral levels, of specialists in a variety of disciplines related to our goals.

Studies fall into the following categories: Developmental Biology, Neurophysiology, Neurobiochemistry and Socio-Behavioral Research. Most of our research efforts are carried out on the UCLA campus. Additionally, a large multi-disciplinary research program exists at the Pacific State Hospital (recently renamed Lanterman State Hospital) in Pomona, California.

PROGRAM FOR THE DEVELOPMENT OF THE MENTALLY RETARDED

R.K. Eyman, University of California, Los Angeles Campus, Neuropsychiatric Inst., Dept. of Psychiatry, *760 Westwood Plaza, Los Angeles, California* 90024 (P01 HD 05540-09)

The proposed research will investigate the effects of residential and educational environments on four sets of outcome variables as they relate to the mentally retarded: (a) mortality and the development of adaptive behavior, (b) personal-social development, (c) cognitive development, and (d) school and home adaptation. The research is based on rigorous investigation of the impact of two powerful and pervasive forces in the provision of services for mentally retarded persons - the principles of normalization and mainstreaming. In addition, the longitudinal study of mortality and changes in adaptive behavior for a five- to ten-year period is suggested to discern developmental trends on a large population of mentally retarded individuals from a number of states.

Four interrelated projects are proposed, each of which has its own specific aims, methods of procedure, and significance. All of them relate to the basic model, and all have as their ultimate objective the discovery of ways to improve retarded individuals' adaptation to their environments.

EFFECTS OF VARNISH AND TRACE ELEMENTS ON ENAMEL FLUORIDE AND DENTAL CARIES

D.H. Retief, University of Alabama in Birmingham, School of Dentistry, Dept. of Biomaterials, *1919 7th Ave. S., Birmingham, Alabama* 35233 (P50 DE 02670-130036)

One of the objectives is to evaluate in vitro and in vivo fluoride uptake by enamel from topical fluoride varnishes. Calcium fluoride is the main reaction product when topical fluoride agents are applied to enamel surfaces. Fluoride-containing varnishes have been introduced to prolong the contact time of topically applied fluoride to enamel and thus promote the formation of fluoroapatite.

The application of fluoride-containing varnishes to enamel resulted in significantly increased fluoride uptake, distribution and retention when compared to acidulated phosphate fluoride. An interesting finding in this in vitro study was that the fluoride uptake by enamel was inversely related to the fluoride concentration of the enamel prior to topical fluoride application.

The relationship between enamel fluoride content and caries experience in a community living in an endemic fluoride area with fluoride content in the drinking water of 3.2 ppm was determined. A highly significant positive association between caries experience and enamel fluoride concentration was established.

It is proposed to further investigate the acquisition of fluoride by enamel after treatment with fluoride-containing varnishes. Particular attention will be paid to the retention of the acquired fluoride after prolonged immersion in synthetic saliva and the effect of more frequent topical applications on fluoride uptake.

The caries inhibitory effect of the fluoride-containing varnishes will be evaluated in the rat, and attempts will be made to relate caries inhibition with enamel fluoride concentration.

3.1051,
PERIODONTITIS AND HOST DEFENSE IN JUVENILE DIABETES

B.H. Park, State University of New York, Health Science Center at Buffalo, Childrens Hospital of Buffalo, Dept. of Pediatrics/Microbiology & Immunology, *219 Bryant St., Buffalo, New York* 14222 (R01 DE 05505-02)

Patients with diabetes often suffer from undue infection. Juvenile diabetes (insulin-dependent diabetes mellitus - IDDM) is one form of diabetes which affects mainly children and young adults. Some of these young diabetics are known to have particular difficulty in controlling their diabetes and consequently have more complications of diabetes. One of the complications, which precipitates the so-called 'diabetic ketoacidoses' is infection; some overt, others hidden unnoticed.

We have found that more than 20% of young adult (12 years or older) diabetics have periodontal infection with bone loss (jaw bone) demonstrable X-ray examination. The onset of the periodontal complication appears to coincide with puberty, related to poor dental hygiene and to poor control of their diabetes.

We plan to examine further the exact nature of the periodontal complications in our juvenile diabetes patients with regard to: 1) What is the natural course of the development of the periodontal disease, a longitudinal study? 2) What microbial agent is responsible for the development of the infection? 3) How can these lesions be treated? 4) How can these complications be prevented? 5) What defect in immunological, host defense mechanism can be associated with the development of periodontal complication?

3.1052,
PSYCHOMOTOR IMPAIRMENT RELATED TO N2O EXPOSURE

P.A. Moore, Harvard University, Boston Campus, Harvard School of Dental Medicine, Dept. of Oral Biology, *188 Longwood Ave., Boston, Massachusetts* 02115 (R23 DE 05507-01)

In an effort to determine the risk involving exposure to nitrous oxide (N2O), this research proposal is designed to define the psychomotor impairment related to the exposure of humans to N2O. The work during the first year of this project will involve constructing a testing chamber where the concentration of N2O can be carefully controlled and monitored. A forced choice, audiovisual reaction time testing apparatus for evaluating the psychomotor impairment will be designed and its accuracy and sensitivity will be evaluated. Following development of this testing environment, healthy young adults will be exposed to various concentrations of N2O and the dose dependent decrease in function will be determined. The lowest concentration of N2O that induces impairment (threshold) will also be determined. This initial work will serve as baseline data for the studies of the second and third year of the project. The changes in threshold and dose vs. impairment relationship will be determined following prolonged exposure to low concentrations of N2O (a situation similar to occupational exposure) to repeated high concentrations of N2O (a situation similar to recreational exposure). Changes in the rate of recovery following N2O exposure will be determined following therapeutic exposures of long and short duration. Recovery will be similarly evaluated following different concentrations of therapeutic exposure. The results of this study will be valuable in constructing guidelines for the safe use of N2O in dentistry.

THE EFFECT OF SCHOOL WATER FLUORIDATION ON DENTAL CARIES

S.B. Heifetz, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Dental Research, Community Programs Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 DE 00029-13 CPR)

Fluorides were added to the water supply of a school in Seagrove, North Carolina. The concentration of fluoride used was higher than the level considered optimal for the community water fluoridation in the geographic area. Children attending the Seagrove school live in an area without a central water supply and where the various sources of well water contain negligible levels of fluoride. Children are exposed to the higher fluoride level only while at school in an attempt to approximate the total fluoride intake of children who drink optimally fluoridated water on a full-time basis. Baseline dental examinations for dental caries were made prior to the installation of fluoridation equipment. Follow-up examinations were conducted after four, eight, and twelve years to determine the extent of caries protection as increasingly larger segments of the study population become continuously exposed to fluoridated water at school since entering the first grade. Results of the four- and eight-year examinations on full beneficiaries of the procedure showed decreases in caries prevalence of 30 and 40%, respectively, compared with baseline findings. On the eight-year examinations, an assessment of the prevalence of dental fluorosis showed that no children had any definite signs of the condition.

3.1054,

ASSOCIATION OF STREPTOCOCCUS MUTANS WITH DENTAL CARIES REDUCTION IN A SCHOOL POPULATION

L.A. Thomson, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Dental Research, Etiology Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 DE 00228-04 CPR)

Dental plaque is being studied to determine whether changes in microorganisms, specificially Strep. mutans, occur during fluoride preventive procedures. The school population consists of children using fluoride rinses either daily or weekly, as well as some children using placebo solution. Dental plaque samples are obtained periodically and analyzed using cultural methods and fluorescent antibody reagents specific for bacteria under study. Plaque samples were obtained at the following times: Fall, 1976, Spring, 1977, Fall, 1977, and Fall, 1979. Saliva samples were also obtained during the 1979 examination. Alterations in plaque composition during the study period will be compared with the changes in the caries incidence.

3.1055,

PREVALENCE OF DENTAL CARIES AND DENTAL FLUOROSIS IN AREAS WITH OPTIMAL AND ABOVE OPTIMAL CONCENTRATIONS OF FLUORIDE IN THEIR WATER SUPPLIES

H.S. Horowitz, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Dental Research, Community Programs Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 DE 00277-01 CPR)

In 1980, a cross-sectional survey to measure the prevalence of dental caries and dental fluorosis was conducted in several study sites served by public water supplies that contained natural fluorides at approximately the optimum recommended concentration and at two, three and four times the optimum. Only children who were continuous residents since birth at each site and who used the public water supply as their primary source of drinking water were included in the survey. About 800 children, ages 8-15 years, were examined. Dental caries was assessed with the DMF surface index and dental fluorosis was measured traditionally with Dean's Index and with a newly developed tooth surface index of fluorosis (TSIF). Fluorosis was assessed independently in each child by each index. In addition, color photographs were taken to depict varying degrees of fluorosis.

GENETIC POLYMORPHISMS OF SALIVA

E.A. Azen, University of Wisconsin, Madison Campus, Medical School, Dept. of Medicine, *450 N. Randall Ave., Madison, Wisconsin* 53706 (R01 DE 03658-16)

We will identify new genetic polymorphisms in saliva using a variety of electrophoretic and staining methods with special emphasis on isoelectric focussing. Major components and defined systems will be studied first followed by fractionation of saliva and radiolabelling of trace components. We will extend linkage studies of genes for proline-rich proteins to include six loci (Pr, Dd, Pa, Gl, Pm and Ps). The gene order and map distances will be estimated and an attempt will be made to assign the cluster of genes to a chromosome by linkage studies with a variety of known genetic markers. We will extend epidemiologic studies, showing a relationship between phenotypes in the polymorphic systems and dental disease, by increasing the population base and including several new genetic markers (Gl, Pm, and Ps) in the analysis. We plan to develop a program at the University of Wisconsin through collaborative arrangements, for the molecular cloning of the proline-rich protein gene complex in humans.

SELECTED FACTORS INFLUENCING INCIDENCE OF ORAL CLEFTS

J. Niebyl, Johns Hopkins University, School of Medicine, Dept. of Obstetrics & Gynecology, *725 N. Wolfe St., Baltimore, Maryland* 21205

A study to determine the feasibility of studying high-risk mothers (mothers who have given birth to cleft children previously) with respect to potential environmental and metabolic etiological factors affecting their children prenatally and resulting in oral clefts. The final target of such research would be to identify a large-scale high-risk group of mothers and to reduce the risk by modifying prenatal circumstances. The first step in the development of a preventive program for congenital cleft lip and palate will be to identify likely etiologic factors and explore a small population to determine the needs and objectives of a larger study.

THE BIOLOGY OF THE PERIODONTIUM IN HEALTH AND DISEASE

B.M. Levy, University of Texas, Health Science Center at Houston, Dental Branch, Dept. of Pathology, *6515 Freeman, Houston, Texas* 77025 (P01 DE 02232-10)

Research on the biology of the periodontium of various primate species from man to marmosets will be performed in a coordinated multidisciplinary program. The target is the control of human periodontal disease through an understanding of the basic disease processes. The basic objective of the program-project is the study of the periodontium as a biological unit in health and disease. Multidisciplinary and interdisciplinary experiments are designed to elicit the responsiveness of the periodontium to changes in its biological environment. A three-pronged interdiecipllnary attack on the problems of periodontal disease, designed to estabish the manner in which (I) environmental factors, (II) conditioning factors and (III) mediating factors interact to produce inflammatory periodontal disease in men and other primates has been developed. Thus, a solution to the complex health problem, periodontal disease, is being sought through coordinated research on multiple and interdisciplinary aspects of the problem. The effectiveness of the program is critically dependent upon the contribution of each member of the research team. The disciplines represented are: bacteriology, biochemistry, electron microscopy, histology, immunology, immunopathology, nutrition, oral physiology and virology.

CENTER FOR CRANIOFACIAL ANOMALIES

S. Pruzansky, University of Illinois, Medical Center at Chicago, Abraham Lincoln School of Medicine, Dept. of Pediatrics, *1853 W. Polk St., Box 6998, Chicago, Illinois* 60680 (P01 DE 02872-12)

The Center for Craniofacial Anomalies of the A. Lincoln School of Medicine of the University of Illinois Medical Center at Chicago is a multidisciplinary organization that provides comprehensive care for patients with congenital, developmental, and acquired malformations. The Center contributes to special training programs in the health sciences and conducts clinical and laboratory research. The major research thrust is a continuing longitudinal growth study of the natural history of various malformations. The data base includes case histories, photos, study cases, cephalometric and tomographic radiographs, audiometric and speech records on approximately 5500 subjects. Current projects focus on the epidemiology and genetics of congenital palatopharyngeal incompetence and auricular and juxtaauricular malformations in isolation and in syndromes. Early treatment of serous otitis in children with cleft palate is being investigated under controlled conditions. Results of craniofacial surgery for orbital hypertelorism, Apert and Crouzon syndromes, hemifacial microsomia, and mandibulofacial dysostosis are evaluated in terms of subsequent growth and functional studies involving eye motility, vision, speech and hearing. Screening programs are underway to determine the frequency of ophthalmopathy in patients at risk for retinal detachment (Robin and Stickler syndromes). Clues derived from clinical investigation have led to electronmicroscopic studies in ectodermal dysplasia and abnormalities of mucopolysaccharide mechanisms. Family studies on congenital palatopharyngeal incompetence and auricular malformations are underway to allow estimates of recurrence risks. Brain stem electric response audiological studies in infants with craniofacial anomalies and controls have been initiated as part of a developmental study.

PSYCHOPHYSIOLOGY OF TMJ & OTHER FACIAL PAIN SYNDROMES

D.M. Laskin, University of Illinois, Medical Center at Chicago, School of Dentistry, Dept. of Oral & Maxillofacial Surgery, *1853 W. Polk St., Chicago, Illinois* 60680 (R01 DE 02899-11)

This research program emphasizes the psychological and physiological factors in the etiology and treatment of myofacial pain-dysfunction (MFD) syndrome and the objective evaluation of various physical, pharmacological and psychological modalities used for the management of this condition. Historical, physical and psychological data on patients with other atypical facial pain syndromes are also being collected with the ultimate objective of analyzing many of the same factors that initially led to a better understanding of MPD syndrome. Investigations of organic temporomandibular joint disorders are also continuing since their etiology must be understood in order to establish a rational approach to prevention and cure.

GENETIC AND EPIDEMIOLOGICAL STUDY OF SALIVARY PROTEINS

R.D. Friedman, Temple University, School of Dentistry, Dept. of Biochemistry, *3223 N. Broad St., Philadelphia, Pennsylvania* 19122 (R01 DE 04279-02)

Human parotid saliva contains many acidic proteins which are genetically determined. Studies have indicated that certain acidic salivary proteins absorb onto enamel surfaces, and that these proteins could be involved in the organization and development of the plaque matrix. The purpose of this study was to investigate the possible influence of salivary phenotype on individual proclivity to develop dental plaque, periodontal disease and/or caries. Each subject was clinically examined to determine their DMFS score, periodontal and dental plaque indices. A parotid saliva sample was collected for phenotyping. Pr and Db salivary phenotypes were analyzed with data obtained from 63 Caucasian subjects by one-way analysis of variance. Subjects that were phenotypically Db plus had a significantly (P less than 0.05) higher plaque index and higher periodontal index than Db-individuals. Thus far correlations were not discerned between Pr phenotypes and clinical observations. Chi-square analysis showed a disproportionate number of individuals with both Pr 1-2' and Db-phenotypes. There are indications that Caucasian individuals with the Db plus phenotype are more prone to developing dental plaque with concurrent periodontal disease.

LONGITUDINAL STUDY OF DENTAL ROOT SURFACE CARIES

R.P. Ellen, University of Toronto, Dept. of Clinical Sciences, *Medical Sciences Bldg., Toronto, Ontario, Canada* M5S 1A8 (R01 DE 04464-03)

A 3-year longitudinal clinical research project is proposed to study the incidence of root surface caries and the microbial flora associated with the initiation of lesions. The elderly population at Parkwood Hospital, London, Ontario, will be studied. A preliminary study of root caries prevalence in this population indicated that a sufficient number of new lesions should develop.

Each of approximately 50 subjects will be examined annually to record 1) plaque accumulation and periodontal inflammation indices; 2) distribution of developing root lesions; 3) distance of lesions from the crest of gingival margins; and 4) gingival recession. Bitewing radiographs will also be taken.

An average of 8 root plaque samples and a saliva sample will be collected from each subject three times annually. The samples will be diluted and plated on non-selective and selective media. After transportation of plates to Toronto, the proportions and isolation frequency of potentially cariogenic bacteria in the total cultivable flora will be determined, with special reference to Streptococcus mutans, Actinomyces viscosus, Actinomyces naeslundii, lactobacilli, enterococci, and Arthrobacter-like microorganisms.

A bacterial flora profile will be incorporated in the general computer analysis to determine the relationship of the degree of odontopathic infection and the clinical parameters measured. The degree of association of both bacterial and clinical parameters with the initiation of root lesions will be calculated. The data should indicate the microbial and periodontal environments which determine susceptibility to root caries or maintenance of root surface health.

PLAQUE BACTERIA AS PREDICTORS OF HUMAN DENTAL CARIES

B.A. Burt, University of Michigan, Ann Arbor Campus, School of Public Health, Inst. of Environmental & Industrial Health, *Ann Arbor, Michigan* 48104 (R01 DE 04504-03)

The study is to assess the extent to which S. mutans, S. sanguis and organisms of the lactobacillus species precede the clinical manifestation of fissure caries. It will also examine, over time the quantitative relationship between these organisms in both clinically sound and in clinically carious teeth. The time sequence of colonization of the organisms, will be related to the development, or absence of development, of clinical caries, and the study will seek to demonstrate microbiological developments that predict the diagnosis of clinical caries with a high degree of probability. This three-year longitudinal study is an epidemiological-microbiological collaboration. The study began with 495 children aged 6-7 in the nonfluoridated community of Coldwater, Michigan, in April 1979. Each child is having samples of dental plaque taken from the occlusal fissures of the mandibular first permanent molars at six-month intervals, and is receiving a dental examination each year. Results of the subsequent bacterial counts are compared with the carious status of the teeth as determined by clinical examinations, and the results from various examination and sampling cycles compared.

A GENETIC STUDY OF HUMAN OROFACIAL CLEFTS

S.W. Oka, Lancaster Cleft Palate Clinic, Genetic Services, *24 N. Lime St., Lancaster, Pennsylvania* 17602 (R23 DE 04537-03)

Family pedigree data on 1178 probands are to be analyzed from a clinical epidemiological and from a genetic orientation. A subpopulation of pedigrees with a positive family history will be focused upon for the initial analysis to test specific genetic hypotheses including the generally accepted multifactorial threshold model.

Previously collected data include dental casts, facial photographs, and cephalograms. The cephalograms which were collected by family groups will be analyzed to compare basi-cranial and C1 and C2 mensurational relationships. This analysis will seek variant patterns of these structures in unaffected relatives. It will also enable a comparison of methodology by measuring these structures from radiographs as well as directly from digitally enhanced cephalograms.

3.1069,

AUTOMATED PHYSIOPRINTING OF FACIAL PATTERN

V. Sassouni, University of Pittsburgh, School of Dental Medicine, Dept. of Orthodontics, *C336 Salk Hall, Pittsburgh, Pennsylvania* 15213 (R01 DE 04584-02)

At this time, there is no practical, accurate, rapid and economical quantitative method of measuring the soft tissue appearance of the face. At the same time, many treatment decisions in orthodontics, maxillo-facial surgery, dento-facial prosthesis, are based on a subjective evaluation of facial balance.

The objectives of this proposal is to combine the physioprint, a standardized photographic technique, with automatic optical scanner to record and compute the facial pattern in three dimensions.

The five-year project is subdivided in the following manner: 1st year: Improvement of the physioprinting and its processing with automated optical scanner for quantitative data collection in three dimensions - Estimate of errors - Reduction of coordinates to the most meaningful ones (Parsimony). 2nd and 3rd Years - Application of the system for the establishment of facial soft tissue 'standards of normality' (in terms of association with normal occlusion) and of facial esthetic standards - These will have a major value for diagnostic and reference purposes. 4th year - Application of the system for the epidemiology of extreme facial variations in order to assess the nature and the severity of the soft tissue deviations. This study may provide criteria to determine 'handicapping malocclusion'. It also may give criteria for distinguishing patients in need of maxillofacial surgery rather than orthodontics. 5th Year - Initiate the application of this technique for the study of treatment effect on the face. This initial start into treatment may be followed by a second five-year project for the application of the technique to the diverse orthodontic, surgical or prosthetic treatment of dento-facial abnormalities.

The advantages of this system are its capabilities in recording, measuring and storing automatically large numbers of three-dimensional facial soft tissue measurements. Because the external soft tissue is closely the expression of underlying bone and teeth, this system may become, in part, a substitute for roentgenographic cephalometry, thus reducing radiation hazard to the population, without reduction of diagnostic information.

WORKSHOP ON THE ETIOLOGY OF FACIAL CLEFTING

D. Bixler, Indiana University, Indiana University - Purdue University at Indianapolis, School of Dentistry, Dept. of Oral Facial Genetics, *1121 W. Michigan St., Indianapolis, Indiana* 46202 (R13 DE 05213-01)

This proposal requests support for a 3-day workshop on the etiology of facial clefting. The meeting place will be the Airlie House in Virginia and participants will be invited. A panel of experts in the fields of teratology and embryology, genetics and mathematics and epidemiology will be presenting formal papers critically reviewing the current status of the

literature with regard to clefts in animals and humans. The emphasis is, however, heavily on the human data. Discussants of each formal presentation will be assigned and the entire workshop discussions and papers tape-recoded. The major topic areas to be considered are: (1) animal model systems (2) human population data (3) mathematical models applied to the etiology of clefts and (4) genetic and phenotypic markers related to clefting. The workshop will conclude with committee reports from each of these areas, and the entire group will make specific recommendations regarding the goals of future research in this area.

DENTAL DISEASE AND WORK LOSS

S.T. Reisine, University of Connecticut, Health Center, School of Dental Medicine, Dept. of Behavioral Sciences & Community Health, *Farmington Ave., Farmington, Connecticut* 06032 (R23 DE 05497-01)

Measures of oral health status have traditionally been based on clinical measures of oral tissue pathology. Despite the growing movement in medicine to conceptualize health status in terms of ability to function in social roles, dental research has given little attention to the effects of oral conditions on an individual's social function level. The purpose of this study is to apply a behavioral approach to oral health status measurement by investigating the effects of oral conditions on work loss.

A prospective telephone survey will be used to collect work loss data on a randomly selected employed population in Connecticut. Data on sociodemographic factors, regularity of care, health insurance and paid work leave will be recorded during the initial interview. Each participant will be re-interviewed quarterly for one year to gather data on incidence of work loss. Data on health-related work loss, both oral and systemic causes, will be collected including work loss due to treatment and preventive visits, pain, anxiety and cosmetic appearance.

The incidence of work loss will be analyzed by major categories of oral and systemic conditions, treatment-related causes and psychological reasons. Incidence will be analyzed on an annual basis and on the basis of quarterly reports to identify seasonal variations. The effects of sociodemographic factors, health insurance and availability of paid sick leave will be investigated to determine if portions of the population are at greater risk or if any of these variables mediate work loss disability.

At the broadest level of concern, this study will provide baseline data on the social impact of oral conditions. This measure of oral health status may be of particular interest to health planners in predicting health care utilization and to social epidemiologists in defining health outcomes.

KINETICS AND TOXICOLOGY OF CADMIUM

J.M. Frazier, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Environmental Health Sciences, *615 N. Wolfe St., Baltimore, Maryland* 21205 (ES00454-11)

The overall objectives of this research project are a) to investigate alterations in mechanical, biochemical, and physiological pulmonary function resulting from chronic inhalation of cadmium at dose levels equivalent to smoking three packs of cigarettes per day; b) to investigate the differences in systematic distribution and toxicity of cadmium in relation to the route of exposure, oral vs. pulmonary; and c) to investigate the mechanisms of pulmonary clearance of cadmium in the rat model.

Experiments involving chronic chronic inhalation of cadmium oxide aerosols (50 and 500 microgram/cu. m x 3 hr/day x 5 days/week x 52 week) and ingestion of cadmium chloride in drinking water (0.5, 5.0, and 50 ppm for 2 years) are being carried out employing male Wistar rats. Pulmonary and renal function tests are being employed to evaluate cadmium toxicity.

METALLOTHIONEIN IN METABOLISM AND TOXICITY OF CADMIUM

Z.A. Shaikh, University of Rochester, School of Medicine & Dentistry, Dept. of Radiation Biology & Biophysics, *601 Elmwood Ave., P.O. Box 607, Rochester, New York* 14642 (ES 01448)

The proposed research will deal with the role of metallothionein in cadmium metabolism as well as toxicity. A radioimmunoassay procedure will be developed to measure metallothionein. Using this procedure, plasma and urine samples from rats experimentally exposed to cadmium and from occupationally exposed humans will be assayed for metallothionein. Renal tubular dysfunction will be correlated with the metallothionein level. Since genetic predisposition for sensitivity to cadmium-induced testicular damage and hypertension has been suggested, this will be evaluated with respect to metallothionein levels in tissues. Inbred strains of mice will be used to study the relationship of metallothionein to testicular damage. Cadmium will be administered by subcutaneous injections.

ENVIRONMENTAL HEALTH SCIENCES CENTER GRANT

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *1 Gustave L. Levy Pl., New York, New York* 10029 (P30 ES 00928-07)

The research program will be focused in seven program areas: effects of low-level, long-term exposure to environmental agents, multiple-factor interactions, environmental cancer, asbestos-associated disease, biological properties of inorganic microparticles, halogenated aromatic hydrocarbons and related chemicals and evaluation of disease potential of new suspect environmental agents. In this we are primarily concerned with human health effects and utilize population studies as an essential methodological approach, with interdigitation of epidemiological, clinical, biological and physical sciences. Because of the recognized need to evaluate the magnitude of the problems studied, environmental evaluation is regularly added to provide quantitative information concerning dose-disease response relationships, to facilitate evaluation of proposals for regulations and control, and prevention of disease. Cooperative studies with occupational groups and identified populations in the general community subject to specific exposures provide an effective approach to such research aims and serve further to build the application of information into the process of seeking the data. Too, such investigations serve to identify groups of people which have been exposed to these agents, i.e., high risk groups. Preventive surveillance becomes feasible, in addition to modification of adverse exposure.

EFFECTS OF SO2 AND RESPIRABLE PARTICULATES ON HEALTH

B.G. Ferris, Harvard University, Boston Campus, School of Public Health, Dept. of Physiology, *55 Shattuck St., Boston, Massachusetts* 02115 (R01 ES 01108-07)

This research is designed to determine whether exposures of human populations to levels of SO2 and particulates around the present ambient standards have an effect on the health of these populations. Random samples of adults and children have been selected in six communities with different levels of pollution and are being followed prospectively. We have completed the first six years and are about to start on our third survey of the adult population. Respiratory symptoms are obtained by means of a standard questionnaire and more objective data from tests of pulmonary function by spirometry. The exposure of the population is measured by data collected from a central station and satellite stations (about 10 per community, both indoor and outdoor). In addition, personal monitors are worn by a number of volunteers at different times of the year to determine how representative the data from the central station are for the exposure to mass respirable particulates.

TRACE CONTAMINANTS:

T.W. Clarkson, University of Rochester, School of Medicine & Dentistry, Dept. of Radiation Biology & Biophysics, *601 Elmwood Ave., P.O. Box 607, Rochester, New York* 14642 (P30 ES 01247-05)

This grant provides core support for a program on trace contaminants with special emphasis on heavy metals. Several interrelated research programs in environmental toxicology have grown to the point at which consolidation into a center offers clear scientific and administrative advantages. The center will provide core facilities in terms of analytical and histopathological laboratories and services in data processing, pharmacokinetics modeling and biomathematics. It will provide resources to develop embryonic research ideas to the point at which independent support may be obtained. The core faculty will provide long-term continuity of professional expertise and experience in the general field of environmental health science, will provide a national resource to respond to urgent needs in its field, and will provide training for new professionals in the field.

The research in the center will be restricted to those trace contaminants most likely to affect human health. In the immediate future, the center will concentrate on the toxic heavy metals (Cd, Hg and Pb), in continuation of well-established projects at Rochester. Since multiple exposures (e.g., dietary methylmercury and selenium from pelagic fish) also occur, the interaction of heavy metals with other substances will be studied as well.

The center will pursue a coordinated program of studies on exposed human populations, on volunteers, and laboratory animals. This program has drawn support in the past, and will continue to draw support from virtually all the classical disciplines available in the medical center.

HEAVY METALS AS ENVIRONMENTAL HAZARDS TO MAN

T.W. Clarkson, University of Rochester, School of Medicine & Dentistry, Dept. of Radiation Biology & Biophysics, *601 Elmwood Ave., P.O. Box 607, Rochester, New York* 14642 (P01 ES 01248-05)

Quantitative estimates of the human health hazards posed by toxic metals in the environment play the key role in setting realistic exposure standards and in devising efficient preventive measures. Three recognized heavy metals provide the focus for this program project: mercury (both as methylmercury and as metallic mercury vapor), cadmium and lead. Since toxicity is typically both defined and determined by multiple factors, the research plan is also multidimensional. It encompasses investigations of the physical and chemical properties of metals and metal compounds that determine how they enter the body; of how they are handled (distributed, metabolized) by the body and its organ systems; of their capacity to impair the processes of reproduction and development; of their action on behavior and the nervous system; of their potential for tissue pathology; of their impact on the health of selected human populations.

AUDITORY EFFECTS OF LONG EXPOSURE TO LOW LEVELS OF NOISE

J.H. Mills, Medical University of South Carolina, School of Medicine, Dept. of Otolaryngology, *80 Barre St., Charleston, South Carolina* 29401 (R01 ES 01301-06)

The major objective is the specification of the qualitative and quantitative facts of noise-induced hearing loss, particularly asymptotic threshold shifts in human observers. A second objective is to specify the audiometric correlates of asymptotic threshold shifts, particularly temporal integration, psychophysical tuning curves, and physiological response assumed to arise from the brain stem and auditory cortex. Groups of human subjects are exposed to noise for durations as long as 48 hours. Measurements are made before, and after the noise exposure as well as during quiet periods interspersed

within an exposure. The exposures are selected in order to evaluate the Equivalent Power Model and/or to noise produce a given temporary hearing loss which can be evaluated with current psychophysical and physiological tests of hearing. Results are expected to have a significant impact on the topic of noise-induced hearing loss and in establishing criteria for the development of the acoustic environment. In addition, many of the methods developed here have immediate application to the diagnosis and treatment of hearing loss and deafness, particularly in infants and young children.

3.1096,
BEHAVIORAL EFFECTS OF LEAD EXPOSURE IN CHILDREN

P.B. Hammond, University of Cincinnati, College of Medicine, Dept. of Environmental Health, *Eden & Bethesda Aves., Cincinnati, Ohio* 45221 (P01 ES 01566-02)

This is a prospective study of the effects of lead exposure on the physical and mental health of children. It is composed of both human and animal studies. The study of children is to be conducted in the natural environmental setting where elevated lead exposure is common. We hope to establish whether and under what environmental circumstances lead causes adverse health effects. Prospective mothers will be recruited into the study during the first or second trimester of pregnancy. Their offspring will be followed for five years. Since many factors are known to influence the behavioral and intellectual development of a child, a multivariate design will be used rather than design which employs a control versus experimental group comparison. Data to be collected on each child include; prenatal and delivery records; physical growth, behavioral and intellectual profiles beginning at 3 days of age and repeated at 9-month intervals; blood lead, FEP, and iron status at 3-month intervals; evaluation of the home environment with respect to quality of child care and sources of lead exposure. The animal studies will use rats exposed perinatally to low levels of lead. Tissue and blood will be monitored for lead and trace metal content. Other measures will include neurotransmitter metabolism, electrophysiological assessment and behavioral evaluation. The animal studies will explore critical periods, persistence and reversibility of toxicity and the utility of hematopoietic indices for identifying individuals at risk for subsequent behavioral impairment. Both human and animal studies will examine the role of age, duration and levels of lead exposure as determinants of effect as well as exploring leads interaction with numerous environmental variables as a determinant of toxicity. The ultimate purpose of all research on neurobehavioral effects of lead is to establish the minimal level of exposure at which effects may occur, as reflected in biological indices e.g., blood lead. A prospective study of the type proposed is necessary to answer crucial questions pertaining to the maximal safe level of exposure at any time in the child's life. Only with such a study can regulatory agencies institute proper control of exposure.

SILICATE, PULMONARY SECRETIONS AND LUNG DISEASE

W.S. Lynn, Duke University, School of Medicine, Dept. of Medicine/Biochemistry, *Box 3711, Durham, North Carolina* 27710 (P01 ES 01581-03)

Characterization and quantitation of foreign substances, secretions and cells which accumulate in airways and interstitium of persons exposed to foreign inhalants and who develop impaired pulmonary functions is in progress. These foreign materials include, in addition to amorphous carbon, several types of crystalline aluminum silicates as well as silica. A major environmental source of these soil-type inflammagens is cigarette smoke but other sources, not yet identified, exist since similar crystals are also found in alveolar macrophages of non-smokers. The toxic effect of these accumulated silicious materials, on isolated alveolar macrophages, cultured Type II cells and pulmonary fibroblasts are in progress. These silicates, when contaminated with cigarette smoke, cause peritoneal macrophages to become cytotoxic against transformed cultured human cells, but do not alter growth rates of human Type II cells or pulmonary fibroblasts.

3.1098,
LONGITUDINAL STUDY OF AIR POLLUTION ON MORTALITY

S.J. Finch, State University of New York, Stony Brook Campus, School of Engineering & Applied Sciences, Dept. of Applied Mathematics & Statistics, *Stony Brook, New York* 11794 (R23 ES 01686-02S1)

This study examines whether reductions in air pollution are associated with reductions in the prevailing mortality rates. The areas considered are census tracts that have 'high' residential stability; this restriction reduces the effect of migration into and out of the area. Analysis of data from Buffalo will be completed by the end of the first year of the project. Next year, data from Detroit, Seattle, and the major cities of Ohio will be analyzed. Results to date from Buffalo support the hypothesis of an association between reduced air pollution levels and a reduction in the prevailing mortality rate; however, these results are not statistically significant. Consideration of the larger data sets will clarify this point. In addition to time trend analyses, the study is examining whether there are any unusual geographical clusterings of mortality rate changes and performing other exploratory analyses. The deaths are analyzed by cause of death to specify the nature of the putative air pollution and mortality association. Primary attention, of course, is given to lung and chronic heart disease.

3.1099,
ENVIRONMENTAL HEALTH SCIENCES CENTER

G.N. Wogan, Massachusetts Inst. of Technology, Harvard M.I.T. Program in Health Sciences & Technology, Dept. of Nutrition & Food Science, *77 Massachusetts Ave., Cambridge, Massachusetts* 02139 (P30 ES 02109-03)

The overall objective is to develop a series of data bases on which assessment of potential health consequences, especially total burden of environmental carcinogens and mutagens, resulting from utilization of fossil fuels can be made more objectively and with greater precision than is currently possible. The program of research has the objective of determining the character and range of potential health effects associated with several technologies for fossil fuel combustion by relating evaluations of a variety of biological responses to critical operating parameters characteristic of existing and alternative combustion equipment.

The ultimate aim is to define conditions of combustion for each of several fuel types which result in the emission of minimal amounts of substances with mutagenic and/or carcinogenic properties. This objective is being approached through the following lines of investigation: (1) Conducting parametric combustion studies using laboratory and larger-scale combustors to determine effects of temperature, equivalence ratio and fuel type on the formation of particulates and polycyclic compounds. (2) Subjecting selected samples from the combustion experiments to exhaustive chemical analysis. (3) Evaluating the biological and biochemical properties of selected samples produced under defined combustion conditions with respect to mutagenicity in bacteria and human cells and ability to form covalent adducts with nucleic acids when activated in vitro and in vivo.

3.1100,
ABESTOS AND CANCER

M.L. Warnock, University of California, San Francisco Campus, School of Medicine, Dept. of Pathology, *551 Parnassus Ave., San Francisco, California* 94122 (R01 ES 02117-02S1)

Our previous studies have failed to demonstrate a relation between numbers of asbestos bodies and the presence of carcinoma of the lung or gastrointestinal tract in workers with very low asbestos exposure. Asbestos bodies, however, represent only a part, and perhaps only a small part, of the total lung asbestos burden, which is composed of coated bodies as well as uncoated fibers. It remains possible that a relation exists between numbers of uncoated asbestos fibers and the presence of bronchogenic carcinoma. This study will attempt to quantify and type the uncoated asbestos fibers as well as asbestos bodies at various sites in the lung. A new preparative method has already been developed and used for examining and identifying the nature of the cores of asbestos bodies by electron diffraction. The same method will be used to identify further these same bodies by electron microprobe analysis. An additional preparative method has been devised for recovering uncoated asbestos fibers. Relations between numbers of coated and uncoated asbestos fibers, as well as their relative locations within the lung, will be tabulated, and an attempt will be made to correlate numbers or types of fibers with the presence or absence of carcinomas. We have previously shown that numbers of asbestos bodies are related to occupation; an attempt will be made to establish whether a similar situation exists for uncoated fibers or whether they are derived from the environment.

3.1101,
RESPIRATORY EFFECTS OF HOUSEHOLD EXPOSURES

G.W. Comstock, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 ES 02157-01S1)

In 1977, 1,950 adult residents of Washington County, MD were examined for respiratory symptoms and impaired ventilatory function by means of standardized procedures. Nearly half of these persons had never smoked; the remainder were cigarette smokers. By matching records from these respiratory examinations against the records from a private census of the county in 1975, it will be possible to identify which of the examined subjects were exposed to smokers in the household in 1975. This will give a close approximation of the 1977 exposure because relatively few persons changed their smoking habits during this two-year period. Other household exposures of possible importance for respiratory findings are respiratory infections in the household oxides of nitrogen, and summer pollens. The effects of these other exposures can be assessed by indirect indices: Probability of respiratory infection by the number of school children in the household; oxides of nitrogen by the use of gas for heating or cooking; and summer pollens by location of residence and the absence of air conditioning. The analysis will compare the frequency of respiratory symptoms and impaired ventilatory function among smokers and non-smokers with and without these exposures, using appropriate statistical adjustments for the effects of other exposures and confounding factors such as race, sex, age and socioeconomic status.

3.1102,
METABOLIC EFFECTS OF LEAD

S. Piomelli, Columbia University, College of Physicians & Surgeons, Dept. of Pediatrics, *630 W. 168th St., New York, New York* 10032 (R01 ES 02343-03)

Studies in the first period of these projects have demonstrated that the measurement of free erythrocyte protoporphyrin is an exquisite indicator of Pb poisoning. Free erythrocyte porphyrins can be measured rapidly and precisely by a micromethod (FEP test).

The proposed research will investigate the clinical significance of hemotological evidence of lead toxicity in asymptomatic children with moderately elevated body burden of lead. These studies will investigate whether, at equal blood Pb levels, more pro-

nounced metabolic effects reflect a greater body burden of lead and greater evidence of neurological toxicity.

These studies will evaluate the different content and the molecular species of protoporphyrin present in red cells fractionated according to age to provide an insight into the temporal sequence of lead exposure at time of testing to be used in diagnosis and treatment. These studies will also evaluate the effect of Fe deficiency on porphyrin elevation.

An epidemiological study will be performed in children, as well as in adults, to substantiate the evidence for a dose-effect relationship between body burden of Pb and metabolic interference. These studies will be performed in individuals with blood Pb in the range presently considered 'normal,' to demonstrate evidence of metabolic effects even in this range.

These studies will investigate the lag phase between exposure of animals to lead and elevation of porphyrins as well as the sequence of production of free and Zn-chelated protoporphyrin.

These studies will evaluate the mechanism of action of lead on the mitochondrial enzyme ferrochelatase and evaluate whether this is a specific effect or an interference with mitochondrial function and Fe transport.

CASE-CONTROL STUDY OF HAIR DYE USE AND BREAST CANCER

B.S. Pasternack, New York University, School of Medicine, Dept. of Environmental Medicine, *100 Washington Sq. E., New York, New York* 10003 (R01 ES 02436-01)

Because of the potential public health importance of the possible association between hair dye exposure and breast cancer, a case-control study has been designed to clarify the previous conflicting findings concerning this issue. About 780 breast cancer cases and 1560 controls will be obtained from a breast cancer screening clinic, and will consist of recent screenees and prospective screenees. The prospective cases will permit a history of hair dye use to be obtained before breast cancer is diagnosed. Latency effects and the confounding effects of other breast cancer risk factors will be taken into account in the analyses. The sample size will be sufficiently large to detect relative risks on the order of 1.3-1.5, and to permit relatively precise estimates of risk. Dose-response relationships and interactions between hair dye exposure and other risk factors will be assessed.

3.1104,
EPIDEMIOLOGICAL RISK MODELING AND ESTIMATION

H.D. Tolley, Battelle Memorial Inst., Pacific Northwest Laboratories, *P.O. Box 999, Richland, Washington* 99352 (R23 ES 02493-02)

The research project proposes to implement and investigate stochastic compartment model methodology as a tool in modeling and estimating epidemiological risk due to environmental stresses. Although not all modeling of risk factors can be accomplished using a compartment model formulation, most epidemiological models of assessing risk currently in use can be quite simply put into this framework. In this setting, both an empirical and a theoretical investigation will be made of the current methods of risk estimation including bias, robustness and statistical power of the tests. Which kinds of hypotheses can and cannot be examined using the various methods will particularly be studied.

The model proposed is easily generalized to represent more complex survival-death processes. This generalization lends itself to the estimation of risk when more specific mechanisms regarding possible environmental hypotheses are proposed. Once such example is the estimation of latency in cancer studies. A second example is in extending the definition of risk to multiple cause mortality data incorporating intermediate as well as underlying causes of death in assessing disease linkage (correlations and causal sequencing). Thus, the second aim is to develop a methodology which will expand the family of risk estimable models from epidemiological data. As in all compartment formulations, however, problems of parameter identifiability are present. Which parameters of these more complex models can be practically identified and the robustness of these estimates under model fluctuations is also to be examined.

3.1105,
WORKSHOP ON BRAIN TUMORS IN THE CHEMICAL INDUSTRY

I.J. Selikoff, New York Academy of Sciences, Environmental Sciences Laboratory, *2 E. 63rd St., New York, New York* 10021 (R13 ES 02621-01)

In November of 1978 the Occupational Safety and Health Administration received a complaint from an employee who stated that he was suffering from a brain tumor and knew of others with the same problem. This spurred a series of epidemiological investigations to determine whether this was a random occurrence or whether these tumors might be related to worker exposure to toxic substances at the plant. At the one facility in question, 18 brain cancer deaths have occurred to date and 25 other cases have been indentified at another plant; similar cases are being reported in petrochemical facilities in other parts of the world. It is our intention to bring together scientists from government, industry, academic institutions and labor to review the current state of the knowledge concerning occupational and environmental etiology of brain tumors. The consideration of currently available data will allow dissemination of state-of-the-art information to researchers throughout the world. It will further serve to assist in evaluation of etiological factors, of particular significance now as measures are considered for control of the problem.

ENVIRONMENTAL HEALTH SCIENCES CENTER GRANT

R.R. Suskind, University of Cincinnati, College of Medicine, Dept. of Environmental Health, *Eden & Bethesda Aves., Cincinnati, Ohio* 45221 (P30 ES 00159-14)

Environmental Health Sciences Center Grant at the University of Cincinnati provides core support for interdisciplinary, in-depth research on environmental health problems of public health significance. The objective is to enhance understanding of environmental hazards affecting human health and components of man's ecosystem so that detrimental affects may be prevented and controlled. The scope of the research effort for which Center resources are used covers a wide range of interests: from molecular aspects of biological effects. Tc the study of populations at risk, as well as identification and quantitation of hazard factors in the environment.

The problem areas for which multilevel approaches are used include: 1) The role of essential trace metals in health and disease as influenced by environmental factors. 2) Health problems of non-essential toxic metals. 3) The behavioral parameters of environmental hazards. 4) The health aspects of energy sources, particularly fossil fuels. 5) The toxicology of plastics and their combustion products. 6) The carcinogenic, mutagenic, and teratogenic aspects of environmental hazards. 7) The toxicologic and health aspects of drinking water contaminants and wastewater factors. 8) Pulmonary metabolism and toxicology of environmental agents. 9) The clinical and epidemiologic study of occupational and community hazards. 10) The identification, measurement and control of environmental contaminants in air, water, wastes, industry, agriculture, consumer products, etc.

3.1107,
CHEMICAL AND BIOLOGICAL DETERMINANTS OF TOXICITY

R.J. Rubin, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Environmental Health Sciences, *615 N. Wolfe St., Baltimore, Maryland* 21205 (P01 ES 00454-12)

This proposal for a program project represents a continuing effort on the part of a multidisciplinary team in studying the basic biological effects of a variety of environmental chemicals. The research team consists of professionals trained in the field of biochemistry, chemistry, physiology, microbiology, engineering, pharmacology, toxicology, morphology and pathology, oncology, and medicine. Included in the proposal are 11 separate research projects dealing with the question of mechanisms and determinants of toxicity induced by environmental chemicals. There are 4 projects dealing with neuro- and behavioral toxicity of compounds such as lead, manganese, methyl butyl ketone, organophosphates and carbon monoxide. Of particular importance in these projects are questions of in utero and neonatal exposure, of simultaneous exposures to multiple agents, and of effects on cerebral blood flow. Three projects deal with pulmonary toxicology of agents such as acrolein, paraquat cadmium, asbestos and fiberglass and deal specifically with effects on lung defense mechanisms and deposition of fibers. One project deals with the toxicology of the phthalic acid esters with emphasis on the lung, liver, and mutagenic potential; another with the toxicokinetics and lung toxicity of cadmium. Two projects deal with genetic toxicology and the potential mutagenicity/carcinogenicity of SO2, nickel, cadmium, and benzene. The objective of all these studies are: (1) to evaluate hazard so as to prevent disease, (2) to develop predictive assays, and (3) to lead to the development of rational therapeutic agents to reverse or prevent toxic effects.

3.1108,
TOXICITY OF ORGANIC MERCURY FOR THE FETUS AND NEWBORN

M.D. Maines, University of Illinois, Medical Center at Chicago, School of Basic Medical Sciences, Dept. of Pharmacology, *1853 W. Polk St., Chicago, Illinois* 60680 (R01 ES 00820-07)

Numerous infants born to women consuming foods contaminated with organic mercury during pregnancy have exhibited severe neurologic sequelae after birth. Because of similarity to the human with respect to reproductive parameters, fetal maturation and placental transport, monkeys (Macaca mulatta and M. arctoides) will be used for the following studies. 1) Localization of methylmercury and sites of damage in the macaque brain are being compared in the fetal and adult monkey. 2) The teratoganic potential of methylmercury in the embryonic macaque will be evaluated. 3) Potential therapeutic measures will be examined where a differentiating organism is involved. 4) Women of child-bearing age also exposed to phenylmercury and mercury vapor. Thus, measurements of placental transfer and fetal toxicity following maternal administration of these substances are to be carried out.

3.1109,
TASTE OF MIXTURES

L.M. Bartoshuk, John B. Pierce Foundation of Connecticut, *290 Congress Ave., New Haven, Connecticut* 06519 (R01 ES 00880-08)

Taste stimuli encountered in the real world like tap water, foods, and beverages are mixtures. The major objective of this study is to provide a framework that will permit the prediction of the taste of a mixture from knowledge of the tastes of its components and the manner in which it was tasted. When taste substances are mixed, their tastes change in intensity even when there are no chemical interactions among

the tastants. The mixture interactions depend in part on the shapes of the psychophysical functions that describe perceived intensity versus concentration and in part on other variables not yet identified. The taste of a complex solution actually comes from two sources: the solutes and the water solvent in which they are dissolved. The taste of water itself depends on the substance to which the tongue is adapted. Water can taste sweet, sour, salty, or bitter if it follows adaptation to appropriate substances. For example, adaptation of NaCl makes water taste bittersour. Under normal conditons, the tongue is adapted to saliva which contains NaCl. The water taste produced by adaptation to saliva contributes to the tastes of mixtures. We propose to study the tastes of complex solutions by 1) identifying the variables that control mixture interactions and 2) determining the contribution of water taste to the tastes of complex solutions. The experiments will be conducted on human subjects with the ratio scaling technique of magnitude estimation, with matching procedures, and with threshold procedures. The results of these studies may suggest ways to improve the tastes of important mixtures like tap water since rules of mixture interactions could be used to predict how the removal or addition of a particular substance would change the taste of the mixture.

OCCUPATIONAL AND ENVIRONMENTAL HEALTH

J.L. Whittenberger, Harvard University, Cambridge Campus, School of Public Health, Dept. of Physiology, *Cambridge, Massachusetts* 02138 (P30 ES 00002-18)

This research, and research training program emphasizes a variety of laboratory studies and epidemiologic approaches to the study of the effects of environmental and occupational factors on the health of man. Specific examples include the following: biology of alveolar macrophages as a pulmonary defense mechanism; effects of breathing pattern and lung volume on the distribution of inhaled particles; development and exploitation of differentiated mammalian cell culture systems to detect, examine the mechanisms of action, and develop means for prevention or reversal of certain environmental chemical toxic agents; development of new chemical and immunologic assay methods for certain classes of environmental chemicals; development and use of affinity probes to identify the sites and molecular mechanisms of action of specific toxic agents; experimental lung cancer; malignant transformation in vitro; cancer morbidity and mortality among rubber workers; pulmonary function changes in granite dust exposures, toluene di-isocyante exposures, and other occupational exposures; the uses of proportional mortality analysis in identifying suspected occupational exposures; a prospective study of children and adults exposed to specific indoor and outdoor air pollutants.

MECHANISMS OF PESTICIDE TOXICITY

E. Hodgson, University of North Carolina, North Carolina State University, School of Agriculture & Life Sciences, Dept. of Entomology, *Raleigh, North Carolina* 27607 (P01 ES 00044-15)

This project has a two-fold component concerning studies directed to biochemical and environmental toxicological research. The biochemical aspects are primarily involved with proteins, specially involved with molecular interactions. Dauterman's project is devoted to a study of pathways of metabolism effected by transferases and includes partial purification of these enzymes. Hodgson's project is an attempt to characterize the several components of P-450 mediated activities, including ligand interaction. Main's effort concerns purification of cholinesterase and kinetic properties of purified enzymes. Moreland's project concerns the effect of herbicides on the sequence of phosphorylative activities in mammals. Guthrie's project is directed to comparative penetration of dermal and oral applications of pesticides and their distribution by blood proteins.

The environmental aspects are divided between studies of the possible genetic effects of a number of xenobiotics and the possible effects on health of agricultural workers who enter fields previously treated with OP insecticides.

3.1112,
STUDIES OF REPRODUCTIVE EFFECTS OF LOW-LEVEL RADIATION EXPOSURE

D.P. Sandler, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Biometry Branch, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 43006-02 BB)

A series of four epidemiologic studies is intended to evaluate the possible effects on human reproduction of low-dose radiation exposure. The individual studies are designed to specifically examine the relationship of radiation exposure to birth defects, spontaneous abortion, fetal and infant death, childhood cancer and human growth and development. Each of the studies focuses on different possible reproductive outcomes, but the studies and the study populations overlap and will provide complementary data. Two general populations are being studied. These are a cohort of nuclear workers (female workers and wives of male workers) who are occupationally exposed to low levels of radiation (external and internal exposures), and a cohort of births to nuclear workers. Data for all segments of the study will be collected using medical records, vital records, subject interviews, employment records or a combination of these sources.

3.1113,
USE OF THE LABORATORY IN STUDIES OF ENVIRONMENTAL EPIDEMIOLOGY

R.B. Everson, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Biometry Branch, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 43008-01 BB)

The long term objective of this project is the effective use of the laboratory in studies of environmental epidemiology. It will include interdisciplinary development of ideas and methodologies, coupled with attention to details of both the laboratory procedures and the gathering and analysis of human data. The effort will focus on the development of techniques identifying possible genetic damage in man by identification of exposures to genetic toxins or disruption of human cellular material suggesting genetic damage.

3.1114,
STUDIES IN PEDIATRIC LEAD EXPOSURE

W.J. Rogan, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Biometry Branch, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 43003-02 BB)

Lead exposure and undue absorption occurs not only in inner city children exposed to paint but also in children around smelters and those whose parents work with lead. Although the encephalopathy and renal disease of acute lead intoxication are well described, other toxicities of lead as well as factors that alter susceptibility need further research. We have begun investigation into genetic differences in susceptibility to the effects of lead on blood formation.

3.1115,
DETECTION OF HUMAN EXPOSURE TO MUTAGENIC SUBSTANCES BY ANALYSIS OF BODY FLUIDS

R.B. Everson, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Biometry Branch, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 43007-01 BB)

The objective of this work is to develop methods for detecting mutagenic substances in human body fluids and to use these methods in studies of environmental epidemiology. Laboratory methods necessary for these studies are currently being investigated and protocols developed for testing model populations. Following clarification of technical issues in these studies, body fluids from individuals suspected to have occupational or other environmental exposure to mutagenic substances will be analyzed to confirm and partially quantitate such exposure.

EPIDEMIOLOGIC STUDY OF REPRODUCTIVE OUTCOMES AND ENVIRONMENTAL EXPOSURES

A. Wilcox, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Biometry Branch, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 44003-03 BB)

This is a long-range project designed to improve epidemiologic methods for studying reproductive outcomes, particularly for studying spontaneous abortion, and to investigate the association between environmental exposures and reproductive outcomes. There are several facets to this project. A comprehensive reproductive questionnaire has been developed, and a study has been designed to test the validity of questionnaire data. The basic epidemiology of spontaneous abortion is being investigated using an extensive, previously-unanalyzed data set. Possible confounders in epidemiologic studies of spontaneous abortion are being analyzed, and questions regarding the underlying biological mechanisms of spontaneous abortion are being examined. Finally, a study of reproductive outcomes among workers exposed to perchloroethylene is being prepared. This solvent is widely used in drycleaning and has been shown in the laboratory to be a mutagen and carcinogen.

RESEARCH IN ENVIRONMENTAL HEALTH SCIENCES

N. Nelson, New York University, School of Medicine, Dept. of Environmental Medicine, *100 Washington Sq. E., New York, New York* 10003 (P30 ES 00260-18)

The NIEHS Center Grant provides core support for the research and teaching program of the Institute of Environmental Medicine. The objectives of the research program are broadly related to the identification of environmental causes of disease, and the development of methods for controlling environmental hazards. The reseach program is an interdisciplinary effort encompassing a wide spectrum of studies ranging from those at the cellular and subcellular level on mechanisms of action, through experimental pathological and physiological and epidemiological studies, to a characterization of environmental transport processes. The NIEHS Center Grant provides salary support for the professional staff of the Institute and limited funds for shared equipment, exploratory studies, and central services. An NCI Center Grant provides complementary, although more limited, support which is exclusively focused on research in the area of environmental carcinogenesis.

NATURAL HISTORY OF HEART, CANCER & STROKE--EPIDEMIOLOGY
L.T. Kurland, Mayo Foundation, *200 1st St. S.W., Rochester, Minnesota* 55901 (P01 GM 14231-15)
The central data bank of the Rochester Program Project (RPP) consists of a file of medical diagnoses and surgical procedures covering the population of Rochester and Olmsted County, MN, for a period of more than 40 years. These data have been assembled from records at Mayo Clinic and other medical care centers and are considered a national resource for epidemiological studies. The medical records upon which this resource depends cover essentially

all local patient-physician contacts and include records for home, outpatient and hospital visits, and autopsy data. This resource is maintained at the Mayo Clinic but is available to visiting scientists, students from other universities, and health agencies.

More than 100 epidemiological studies using this data bank have been completed. These include studies of incidence and outcome as well as case-control comparisons and prospective studies. Recently completed studies include those on pituitary adenomas, carcinoma of the lung, kidneys, ureter, gallbladder and extrahepatic biliary ducts, primary brain tumors, leukemia, rheumatoid arthritis, diabetes mellitus, cerebrovascular disease, stroke, and computed axial tomography brain scan. Underway at the present time are several descriptive epidemiologic studies on ischemic heart disease, retinal detachment, prostate cancer, multiple myeloma, alopecia areata, head trauma, renal stones, and sarcoidosis; case-control studies of leukemia, estrogen use in women with ischemic heart disease, rheumatoid arthritis, fracture risk in diabetics, progestin use in pregnancy, and studies of the use of the CAT scan and total body scans.

SUPPORT FOR STUDY OF INHERITED DISEASES

A.G. Motulsky, University of Washington, School of Medicine, Dept. of Medicine/Genetics, *A-300 Health Sciences Ctr., SC-64, Seattle, Washington* 98195 (P50 GM 15253-13)

This application relates to an interdisciplinary center in medical genetics and inherited diseases. The principal objective is to obtain more fundamental understanding of gene action in man at the level of molecules, cells, individuals and population, and to elucidate the role of genes in the causation of human disease. The Center aims to apply new knowledge to disease prevention and management. Areas to be investigated include: a) biochemical human genetics (proteins and enzymes of formed elements of blood and serum, hemoglobins, pharmacogenetics, developmental genetics); b) genetics of common disorders (coronary atherosclerosis, hypertension); c) genetics of tumor origin; d) somatic cell genetics (X-inactivation, hybridization, complementation, cell cycle mutants); e) cytogenetics (including gametic and early embryonal cytogenetics); f) clinical genetics; and g) statistical genetics.

3.1157,

ANESTHESIOLOGY CENTER FOR RESEARCH AND TEACHING

R.J. Kitz, Harvard University, Boston Campus, School of Medicine, Dept. of Anesthesia, *25 Shattuck St., Boston, Massachusetts* 02115 (P50 GM 15904-13)

We propose an anesthesiology research center consisting of six closely-interrelated research projects supported by a core facility and focused on the mechanisms of actions and aftereffects of drugs used in anesthesia. This will be a multidisciplinary, collaborative effort of basic laboratory scientists and clinicians. Through the center mechanism we will coordinate research groups working at different levels of organization on problems relating to the interaction of anesthetics with excitable tissues. The concepts and mechanisms elucidated through basic studies at molecular and biochemical levels in well defined systems will find application in the applied pharmacology and clinical work of other center investigators.

The six research projects are: 1. Mechanisms of Action of General Anesthetics and Pressure at Cholinergic Synapses. 2. Anesthetic Effects on Neuronal-Glial Central Nervous System Homeostasis. 3. The Role of Calcium in Malignant Hyperthermia. 4. Effects of Anesthetics on the In Vitro Biochemistry of Synaptic Activity. 5. Role of the Renin-Catecholamine-Prostaglandin System in Hemodynamic Performance. 6. Effect of Enkephalins and Endorphins on Anesthesia.

A RESEARCH PROGRAM IN GENETIC EPIDEMIOLOGY

N.E. Morton, University of Hawaii System, Manoa Campus, Population Genetics Lab., *Bachman Hall, Honolulu, Hawaii* 96822 (R01 GM 17173-12)

The five aims of this project are to extend segregation analysis for quantitative traits and attributes underlying such diseases as diabetes, gout, and atherosclerosis, to derive recurrence risks for computer-assisted genetic counseling, to test causal hypotheses relating to unfavorable pregnancy outcomes, to detect new linkages and integrate physical, genetic, and chiasma data into a chromosme map, and to extend path analysis with respect to assortative mating, qualitative data, and various measures of association relevant to common diseases.

3.1159,

STATISTICAL METHODS FOR CASE-CONTROL STUDIES

R.L. Prentice, Fred Hutchinson Cancer Research Center, *1124 Columbia St., Seattle, Washington* 98104 (R01 GM 24472-04)

The aim of this continuing project is the development and evaluation of improved statistical methods for the analysis of case-control data. The case-control study is a primary tool for epidemiological research into the relationship between 'exposure' variables or other risk factors and disease incidence. The methods under development promise more precise and comprehensive evaluation of the effect of such exposure variables and may lead to liberalization of case-control study design.

The main focus of this project is the adaptation of prospective disease incidence models to case-control sampling. Models considered include the proportional hazards regression model, in which exposure and other factors are presumed to affect the (instantaneous) disease incidence rate in multiplicative manner, and the associated logistic regression model in which such factors affect the odds-ratio multiplicatively.

We have developed a conditional likelihood procedure for adapting the proportional hazards model to 'time-stratified' case-control data. Numerical aspects and estimation properties based on this likelihood will be studied under this proposal. A central aim of the proposal is the adaptation of the same model in a form that utilizes the whole time-exposure history of individual study subjects and need not require time-stratified sampling. In addition we expect to complete, under this proposal, ongoing work showing the duality of representation and estimation from prospective and retrospective logistic models. Some non-iterative methods for logistic estimation will also be further studied.

COMPUTER RESOURCE FOR GENETIC EPIDEMIOLOGY

M.H. Skolnick, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Medical Biophysics & Computing, *1400 E. 2nd S., Salt Lake City, Utah* 84112 (R01 GM 27192-02)

The resource uses the availability of genealogical information on the Utah descendents of the Mormon pioneers. A computerized data base of these large pedigrees linked to computerized medical records, death certificates, and genetic marker data creates a unique opportunity for medical genetic research. The objectives of the resource are: (1) to create a data resource for genetic and epidemiological studies, (2) to implement and develop methods for analysis of population based genetic epidemiological data, (3) to make resource available on a national basis to qualitified investigators, and (4) to collaborate with resource users for implementation of disease specific research.

BIBLIOGRAPHIC REFERENCES: Skolnick, M. 1980. The Utah genealogical data base, a resource for genetic epidemiology, in Banbury Report 4: Human Health Data on Defined Populations, J. Cairns, J.L. Lyon, M. Skolnick, eds., Cold Spring Harbor Laboratory, Cold Spring Harbor, New York (in press).

3.1161,

STATISTICAL METHODS FOR FAILURE TIME DATA

R.L. Prentice, Fred Hutchinson Cancer Research Center, *1124 Columbia St., Seattle, Washington* 98104 (R01 GM 28314-01)

This project is designed to mount a substantial attack on a number of practically important topics in the analysis of time to response or 'failure time' date. The methodological starting point for most of the proposed work is the so-called proportional hazards (ph) regression model in which study subject characteristics or exposure variables are presumed to affect the (instantaneous) failure rate in a multiplicative manner. This model is aminable to generalizations and modifications that allow a number of important failure time topic to be addressed. These topics, listed below, are particularly relevant to the analysis of complex epidemiological or clinical cohort studies in which there is limited ability to control the characteristics or exposure variables under study. The topics are also important for therapeutic trials and laboratory experiments, for example, in animal carcinogenesis.

Data analytic topics of emphasis will include (1) theoretical and practical aspects of the use of time-dependent covariates that may record, throughout the observation period, study subject characteristics and exposure levels, (2) the joint analysis of multivariate failure times, as is required when individual study subjects may experience several failure times, (3) the accomodation of multiple failure types or competing risks and, in particular the study of interrelations among failure types and (4) the accomodation of missing covariate data, including circumstances in which the missing data rate depends on the corresponding failure time(s). A number of additional topics will also be considered including the standardization of 'mortality' rates to an external population using the ph model to adjust for demographic characteristics; parameter transformations to improve interval estimation for survival curves; goodness of fit testing for the ph model; efficiency and robustness of ph estimation; and the analysis of very large failure time data sets. Adaptation of methodological developments to case-control study designs and low dose extrapolation studies will also be considered.

3.1162,

STATISTICAL METHODS FOR HEALTH STUDIES

B.W. Turnbull, Cornell University, Ithaca Campus, School of Engineering, Dept. of Operations Research & Industrial Engineering, *242 Carpenter Hall, Ithaca, New York* 14853 (R01 GM 28364-01)

It is planned to carry out an extensive investigation of several areas of statistical methodology for the design and analysis of experimental studies, planned or observational, applicable to various areas of health research including cancer, toxicology, environmental health and epidemiology. The objective would be to provide more efficient statistical methods to achieve valid conclusions at less cost in terms of time and sample size.

Among the problem areas to be considered are: (1) Statistical design and analysis of animal survival/sacrifice studies; (2) Design and analysis of animal cancer induction and treatment studies; (3) Sequential methods for clinical trials (including the topics of screening and early stopping); (4) General statistical problems related to the analysis of censored and incomplete response-time (e.g., survival) data.

THE ROLE OF OCCUPATION IN THE ETIOLOGY OF LARYNGEAL CARCINOMA

J.L. Kelsey, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510

This is a case-control study of white male laryngeal cancer cases seen in the Yale-New Haven Hospital Head and Neck Clinic, newly diagnosed and histologically confirmed between 1977 and 1980. For each case, several white male general surgery admissions (excluding specific diagnoses) who live in the same county and are in the same age stratum as the case will be identified using hospital records. These persons will be briefly interviewed on the telephone to obtain two persons who match the case on smoking. The controls who meet the smoking requirement and who agree to participate will be interviewed in person by a trained interviewer. It is expected that 100-125 cases and 200-250 controls will be evaluated in the study. The subjects will be personally interviewed, preferably in the hospital, but because many will be cases previously seen in the hospital up to 300 may be interviewed in their homes. The risk factors of primary interest are occupational exposures; smoking habits and alcohol consumption will be taken into account in the analysis.

COMPREHENSIVE DISEASE STATISTICS SURVEY

A.G. Schroeder, Westat Inc., Research Division, *11600 Nebel St., Rockville, Maryland* 20852

Westat proposes to conduct a feasibility study for the Comprehensive Disease Statistics Survey. Developmental work for the feasibility study is essentially completed. During the period of this proposed activity, Westat will conduct negotiations with thirty hospitals and train medical record abstractors and reviewers. Data will be collected from the medical records department of the sampled hospitals for approximately 3100 medical records. Westat will process that data, including medical review, and will carry out appropriate quality control. The analysis will cover the comparison of various sampling and non-sampling aspects of the design, the operational feasibility of the plan, and estimated costsof conducting this survey in a larger full-scale pilot test of the survey design. A final report of these findings willbe prepared and submitted to NINCDS.

DEVELOPMENTAL FACTORS ASSOCIATED WITH MENTAL RETARDATION

S.H. Broman, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Developmental Neurology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02106-07 DNB)

The purpose of this study is to identify predictors of mental retardation in a population of 37,000 children followed from the prenatal period to age 7. The incidence of mild retardation (1% in whites and 5% in blacks) and to a lesser degree, of severe retardation (0.5%) was inversely related to socioeconomic status. Among the severely retarded, 25% of whites and 50% of blacks had no major genetic or neurological abnormality. Perinatal risk factors for the severely retarded group as a whole include Down's syndrome, major CNS malformations, neonatal seizures and clinical signs of perinatal hypoxia. For the subgroup of severely retarded with unknown etiology, perinatal risk factors include non-CNS malformations, peripheral nerve abnormalities, signs of hypoxia, and maternal urinary tract infection during pregnancy. A report on teenage pregnancy as a risk factor for poor cognitive outcome has been published. This study is completed and a monograph is in preparation.

ASSESSMENT OF STRATEGIES FOR ANALYZING DATA FROM SMALL AREA MORTALITY SURVEYS

D.W. Anderson, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Section on Surveys & Demographic Studies, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02405-02 OBFS)

Studies of small areas, such as communities or counties, are an important tool of epidemiologists, who are interested in studying the distribution of particular diseases in populations. Many studies of this type have been reported in the scientific literature. An assessment of techniques of analysis frequently used in these studies was initiated to determine their adequacy for use in the NINCDS survey of major neurological disorders in Copiah County, Mississippi (YO1-NS-70031, NO1-NS-7-2357).

PERINATAL INFECTIONS CAUSING DAMAGE TO THE CHILD - COLLABORATIVE PERINATAL PROJECT

J.L. Sever, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Immunochemistry & Clinical Investigations Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 00402-24 ID)

The purpose of this study is to determine insofar as possible the role of perinatal infections in the production of fetal damage. To accomplish this, clinical data and a large number of serial serum specimens have been obtained from the 58,000 women and their children in the Collaborative Perinatal Project. Now that the project is complete, it is possible to study perinatal infections with three main approaches: 1) clinical infections; 2) subclinical infections detected serologically using abnormals and matched controls; and 3) high risk children with elevated IgM levels. Special investigation included the epidemiology of infections and the frequency of congenital toxoplasmosis. Cooperating units work with the Infectious Diseases Branch to study newborns in high risk nurseries. Serum, IgM volumes, plus clinical findings are being used to identify infected infants at risk for perinatal damage. Specific tests are then developed and applied for identification of the infection. Preliminary data indicates that urinary tract infection during pregnancy were found to increase the risk for abortion, stillbirths, neonatal deaths and prematurity.

CHRONIC CENTRAL NERVOUS SYSTEM DISEASE STUDIES - SLOW, LATENT AND TEMPERATE VIRUS INFECTIONS

D.C. Gajdusek, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Laboratory of Central Nervous System Studies, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 00969-16 CNSS)

Studies elucidate cause and pathogenesis of chronic degenerative CNS disorders with emphasis on MS, ALS, parkinsonism-dementia, Parkinson's, Pick's and Alzheimer's diseases, Huntington's chorea, supranuclear palsy, other presenile dementias, chronic encephalitis with focal epilepsy, muscular dystrophies, chronic schizophrenia, SSPE, PML, dialysis encephalopathy, and intracranial neoplasms. Even familial, apparently hereditary, diseases may be slow virus infections. Subacute spongiform virus encephalopathies (kuru and Creutzfeldt-Jakob (CJD) diseases of man; scrapie and mink encephalopathy) are caused by unconventional viruses with unique properties posing important theoretical problems to microbiology and molecular biology; a major goal is elucidation of their structure and mechanisms of replication. Transmissible virus dementias are increasingly recognized worldwide as causes of death: high incidence foci, transmission by corneal transplant or brain surgery, and occupational hazards from exposure to brain occur. In order to determine the usual mode of infection with the virus, a worldwide epidemiological study of transmissible virus dementia (CJD) cases is under way with special attention to familial clusters of cases and with a quest for possible relationship of scrapie of sheep to the human disease.

SELECTED MATERNAL FACTORS AND CONGENITAL CARDIOVASCULAR ANOMALIES

L. Bajda, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Birth Defects & Genetic Disorders Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 01163-18 DNB)

This study, using data form the NINCDS Collaborative Perinatal Project, investigates the relation of selected factors which may affect the mothers during pregnancy, and possible cause congenital heart defects in the children. Observations on about 47,000 pregnancy records provide case and control data for analysis. Some 486 children have been identified as having definite congenital cardiac anomalies. These include cardiac conditions which are part of known syndromes but exclude children suspected of having ventricular septal defect who are reported without cardiac defect at the 1-year examination and thereafter. Pre-selected maternal risk factors noted in the pregnancy records for the mothers of 392 children with definitely defined congenital heart anomalies are compared with control data matched for maternal age, race, date of LMP, and geographical location (institution).

NEUROBIOLOGY OF POPULATION ISOLATES - GROWTH, DEVELOPMENT, BEHAVIOR, LEARNING AND DISEASE PATTERNS IN PRIMITIVE CULTURES (ABBREV)

D.C. Gajdusek, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Laboratory of Central Nervous System Studies, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 01282-16 CNSS)

Studies of human biology of vanishing primitive societies focus on neurological development and learning patterns in diverse cultural experiments in the human condition found in such isolated groups. Laboratory techniques of molecular biology, immunology, virology, endocrinology and biochemistry in these cultures and field epidemiological, genetic and clinical studies are aimed at problems more appropriately studied in small isolated prrmitive bands than in civilized societies. Data and specimens collected over years on expeditions to Micronesia, Polynesia, Solomon Islands, New Hebrides, New Guinea, Indonesia, S. America, Asia and Africa are used. Studies on nutrition, reproduction, fertility, neuroendocrine influences on age of sexual maturation and aging, genetic polymorphisms, genetic distance, unusual and odd employment of the higher cerebral CNS function of language learning, cognitive styles, computation (calculation without words or numbers), and culturally modified sexual behavior elucidate alternative forms of neurologic functioning for man which we would be unable to investigate once the natural cultural experiments in primitive human isolates were amalgamated into the cosmopolitan community of man. Foci of high incidence prevalence kuru, ALS/PD, epilepsy, other neurological degenerations, hysterical disorders, schizophrenia, neoplasms, goiter, cretinism, rheumatoid diseases, diabetes, goit, asthma, chronic lung disease, malaria, filariasis, leprosy, cysticercosis and other infections are investigated.

AN EXAMINATION OF SPEECH AND HEARING PROBLEMS AS DETECTED IN HANES II

C.L. Ludlow, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Section on Surveys & Demographic Studies, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02402-02 OBFS)

The Communicative Disorders Program anticipates conducting a survey of speech disorders among 2-6 year olds. Current work is focusing on constructing a valid test instrument. Concurrently, our Office is assisting in examining similar work done by the HANES II. We intend to use the experience and results from the HANES to determine the feasibility of the survey and what problems should be avoided. We are also exploring the possibility of conducting the survey as part of a future phase of the HANES.

A review of the Hanes Project was undertaken. The investigators have determined that the NCHS methodology is not applicable to our work and that we will have to develop an independent approach. This project is therefore concluded.

ANTENATAL INFLUENCES ON NEUROBIOLOGIC ABNORMALITIES

R.L. Naeye, Pennsylvania State University, Milton S. Hershey Medical Center, School of Medicine, Dept. of Pathology, *500 University Dr., Hershey, Pennsylvania* 17033 (R01 NS 16403-01)

It is proposed to use data from the Collaborative Perinatal Project of the NINDS to determine if abnormalities in the placenta can serve as predictors of long term neurologic, sensory and cognitive abnormalities in children. The study collected sequential

neurologic, cognative and sensory data on children from the newborn period to eight years of age. We examined nearly 35,000 placentas from this NINDS study to standardize the recognition and recording of specific abnormalities. In addition, more than 1000 pieces of clinical information were prospectively collected for most of the cases. Included were data on events of gestation, labor, delivery and the neonatal period.

We propose to correlate each of the long list of placental abnormalities with a battery of test data detailing children's psychomotor, cognitive and sensory abnormalities and development starting in the neonatal period. Several methods will be used to determine if the associations between placental findings and neurobiologic impairments revealed by the analyses are biologically valid or are the result of chance or of the interactions of more than 100 non-placental factors that can affect psychomotor and sensory development. These methods include: (a) log linear model analysis of 3-way contingency tables, (b) discordant sibling pairs, (c) longitudinal analyses of children with and without developmental abnormalities, (d) cross validation determined by analyzing half of the data base and then replicating the analyses on the second half of the data base.

SENILE DEMENTIA - ALZHEIMER AND VASCULAR

R. Katzman, Yeshiva University, Bronx Campus, Albert Einstein School of Medicine, Dept. of Neurology, *1300 Morris Park Ave., Bronx, New York* 10461 (R01 NS 17156-01)

Several major aspects of senile dementia are to be investigated in this project: The Alzheimer type (SDAT) accounts for about 50%, and the munti-infarct type (MID) for another 25% of the cases of this disorder, of which there are more than one million severe examples in this country. Studies of possible etiological factors in SDAT will include analysis of the transmission and nature of the agent that induces intraneuronal paired helical filaments (PHF) in tissue culture of nervous system neurons treated with aqueous extracts of Alzheimer brain. The effects of infection caused by lymphocytic choriomeningitis virus (LCMV) in cultured neurons will be studied and a search made for evidence of LCMV infection in Alzheimer's disease. Neuropeptides in cortex and deep nuclei in autopsy brain specimens from patients with SDAT, MID, and age-matched normal (AMN) controls will be measured by radioimmunoassay and mapped, using immunocytochemical techniques. Morphometric studies involving both cell and lesion counts will focus upon differences between brain showing primarily senile plaques in cortex and those showing neurofibrillary tangles and plaques, and upon involvement of deep nuclei in SDAT, and will be correlated with analysis of choline acetyltransferase (ChAT) as well as neuropsychological data. Additional neuropsychological studies will seek to identify changes characteristic of SDAT and tests that will improve diagnostic accuracy of SDAT and MID. Mechanisms of learning and memory in groups of normal and demented elderly will be investigated. A large prospective study involving 450 elderly (age 75 to 85) volunteers will seek to identify risk factors that predispose to MID.

Thus this program involves studies on diagnosis, treatment, pathogenesis, and etiology of the two major forms of senile dementia.

CLINICAL AND VIRAL STUDIES OF SUDDEN HEARING LOSS

W.R. Wilson, Harvard University, Boston Campus, Massachusetts Eye & Ear Infirmary, Dept. of Otolaryngology, *243 Charles St., Boston, Massachusetts* 02114 (R01 NS 15629-02)

The goal of this proposal is to achieve an increased understanding of the etiology and treatment of idiopathic sudden hearing loss by the systematic collection and evaluation of clinical data.

Our objectives include the serologic evaluation of acute and convalescent sera for the purposes of identifying the principle virus(es) responsible for SHL, and the determination of the relationship between virally induced SHL, to other pathological, demographic, or environmental factors. In addition, we will continue a collaborative clinical study at MEEI, WVU, and K-P Oakland assessing the relationship of ISHL to hereditary, epidemiological, and occupational factors by means of statistical analysis of data obtained from ISHL patients. Also, we will assess the relationship between microvascular disease, diabetes mellitus, and sudden hearing loss. Finally we will determine the correlation between electronystagmography, Hallpike Caloric testing, vestibular or cochlear injury, and the etiology and the degree of loss and recovery from SHL.

The significance of these studies is to increase our understanding of the etiology, classification, and treatment of sudden hearing loss, as well as to lend further insight into the pathophysiologic mechanisms of sensorineural hearing loss in general.

HEREDITARY ASPECTS OF THE EPILEPSIES

M.L. Rivas, Good Samaritan Hospital & Medical Center, Dept. of Research, *1015 N.W. 22nd Ave., Portland, Oregon* 97210 (R01 NS 15820-03)

The objective of this study is to facilitate investigations into the genetic etiology of the epilepsies with emphasis on the spike-wave epilepsies and, in particular, petit mal absence. We propose to study the genetic transmission of these disorders through intensive studies of kindreds ascertained through a proband with a verified epileptic condition.

The study utilizes two unique resources namely, (1) clinical records on 4,000 patients with a seizure disorder who were evaluated at the principal (and for a long time, only) neurological referral center in the Northwest during the period 1938 to 1963 and (2) EEG records on 8,000 individuals tested in the same period of time. Availability of these records permits the record linkage of clinical, laboratory (EEG) and genetic information.

Probands will be selected from individuals evaluated in the Child Neurology Clinic (Epilepsy Center of Oregon), the Genetics Clinic (UOHSC) or in private practice and from individuals evaluated in the Neurological Clinic between the years 1938 and 1963. Systematic collection of clinical, genetic and laboratory (EEG) data will be extended to first, second and third degree relatives of probands. Special emphasis will be placed on record linkage of families to insure completeness and accuracy of pedigree and clinical information. The body of data thus generated will be the basis of more extensive family/genetic studies and be subjected to rigorous genetic analyses and tests of goodness of fit to various genetic models (hypotheses) using recently developed, statistically powerful, computer-adaptable methods.

OTITIS MEDIA RESEARCH CENTER

C.D. Bluestone, Childrens Hospital of Pittsburgh, Dept. of Otolaryngology, *125 De Soto St., Pittsburgh, Pennsylvania* 15213 (P01 NS 16337-01)

Otitis media (OM) is the most common diagnosis made by physicians who care for children, constituting a major health problem in this country. In addition, the state of the knowledge on the subject of OM is lacking in many respects. The epidemiology, natural history, pathogenesis, etiology, diagnosis, management and outcomes of OM are not well established and a significant amount of work lies ahead before these areas can be defined and understood. With this application the University of Pittsburgh -- specifically the Children's Hospital of Pittsburgh (CHP) -- is proposing to establish an Otitis Media Research Center. The core of the proposed center is a series of clinical research studies variously designed to study the efficacy of treatments of OM according to disease stage: acute, recurrent acute and chronic OM with effusion. Some of these clinical studies are currently in progress at CHP, while funding is being sought for others. In addition to these projects are twelve integrated but independent Center projects dealing with various aspects of OM. Preliminary work in these project areas has been well established by the investigators and will form the basis of each proposal. The proposed Center will allow: basic scientists to interact with clinician-scientists in a more intense and formal manner than possible in the past; important questions regarding OM to be answered in an organized manner; patients to flow smoothly from one study to the next depending upon disease stage; the research team to concentrate on research for a reasonable period with financial support; an opportunity to conduct studies, analyze data and publish findings, all leading to the next steps in the development of an organized research approach; this research to be accomplished at a funding level significantly lower than that required for individual research efforts. The presence in Pittsburgh of an experienced, committed research team coupled with the facts that the institutions involved have demonstrated support, adequate clinical and basic research facilities are available, a sufficient number of subjects is attainable, and that patient referral patterns are well established all clearly suggests that the proper time for establishing an Otitis Media Research Center is the present.

AMINOGLYCOSIDE OTOTOXICITY DETERMINANTS

W.E. Fee, Stanford University, School of Medicine, Dept. of Surgery, *300 Pasteur Dr., Stanford, California* 94305 (R01 NS 14596-03)

Considering that one million patients per year are at risk, human aminoglycoside ototoxicity is not as well understood as it ought to be. This project seeks to develop rapid screening criteria to predict and prevent ototoxicity. In addition, it will determine how radioenzymatic serum aminoglycoside levels best correlate with development of toxicity, what clinical factors predispose to ototoxicity, to determine the incidence of ototoxicity in the various clinical infectious situations reflecting the use of this drug group, and to identify comparable patient groups by computer analysis in an effort to make comparative evaluation of the toxicities of the different aminoglycosides under similar clinical conditions.

Human subjects will undergo a detailed history and prospective determination of vestibular and cochlear function by electronystagmography and audiometry respectively. Renal function will be assessed utilizing creatinine clearances and serum BUN. Follow-up evaluation will be performmd in three months to determine development of delayed ototoxicity or recovery from ototoxicity.

Data analysis will be performed via the Stanford Center for Information Processing IBM 370/168 computer utilizing program language SPSS, version 7.0.

EPIDEMIOLOGY OF PROLAPSED LUMBAR AND CERVICAL DISCS

J.L. Kelsey, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (R01 NS 15230-03)

This is a case-control epidemiological study of prolapsed lumbar inter-vertebral disc and prolapsed cervical intervertebral disc. Demographic characteristics

and exposure to possible risk factors in surgical, probable, and possible cases of each of these conditions in the age range 20-64 years will be compared to demographic characteristics and exposure to possible risk factors in two control groups in the same age range. One control group will be composed of people without known spinal disorders and the second will comprise people with back and neck problems other than prolapsed discs. Information on demographic variables and exposure to possible risk factors is obtained by means of a structured questionnaire administered by trained interviewers. The questionnaire covers symptoms of current and previous back, neck, log, and arm problems; respiratory symptoms; exdemographic variables; pregnancy history; occupational history; driving motor vehicles on the job; driving other than on the job; use of other modes of transportation; participation in certain sports; handedness; height; weight; and disability and limitation of activity. The data collection is expected to be complete in the Fall of 1981.

EPIDEMIOLOGIC STUDIES OF IMMUNE FACTORS IN MS

R. Detels, University of California, Los Angeles Campus, School of Public Health, Dept. of Epidemiology, *405 Hilgard Ave., Los Angeles, California* 90024 (R01 NS 10186-08S1)

The objective of this grant was to investigate the pathopoiesis of multiple sclerosis (MS) by conducting five studies using two populations of MS patients, one in a high prevalence area and one in a lower prevalence area. These studies include a cohort study of the natural history of MS in the two areas; an immunologic study of changes in immune status, clinical course and environmental exposures; a genetic study of families with multiple cases of MS; and a case-control study of patients and susceptibility matched siblings. Studies completed to date have suggested the existence of a multiple sclerosis susceptibility gene located on the sixth chromosome and a relationship between haplotype and mean measles titers in MS patients and their normal siblings. Data from the immunologic study suggest that patients have higher mean antibody titers and impaired cell-mediated immunity to measles.

The relationship of immune differences to changes in clinical status and the relationship between immune responses and genetic types will be further studied; the rate of progression to disability, mortality and other factors will be compared between the two cohorts; and analysis of the case-control study will determine factors which are associated with disease.

ETIOLOGY AND PATHOGENESIS OF MULTIPLE SCLEROSIS

H. Koprowski, Wistar Inst. of Anatomy & Biology, *36th & Spruce Sts., Philadelphia, Pennsylvania* 19104 (P50 NS 11036-08)

We will attempt to establish the etiology and pathogenesis of multiple sclerosis using several interdependent approaches. This objective is divided into four areas: 1) the isolation of mammalian oligodendrocytes; 2) analysis of glial cell plasma membranes; 3) virus infection and demyelinating diseases; and 4) immunologic mechanisms of demyelinative CNS disease.

We will use immunologic techniques in an effort to determine the target antigen(s) in oligodendrocyte membrane which interacts with serum from patients with MS. We will characterize other circulating immunologic factors, including antibodies to lipid haptens and alterations in circulating immunocompetent cells. We will carry out similar studies in cells derived from cerebrospinal fluid of patients with MS as one approach to studies of the compartmentalization of the immune response in patients with MS. We will study the biosynthetic processes occurring in isolated oligodendrocytes and in glial cells and the factors which influence those processes.

We will attempt to repeat the successful induction of CNS disease in sub-human primates inoculated with material from patients with CNS disease and study viruses isolated from these primates. We will study the mechanisms of resistance and susceptibility to latent virus infections in the CNS. Mechanisms of humoral and cell-mediated immunological reactions in patients and in animal models will continue to be explored. Viruses isolated in the course of these experiments will be characterized by immunological and biochemical techniques.

EXTRACRANIAL/INTRACRANIAL ARTERIAL ANASTOMOSIS STUDY

H.J. Barnett, University of Western Ontario, Dept. of Clinical Neurological Sciences, *1151 Richmond St., London, Ontario, Canada* N6A 3K7 (R10 NS 14164-04)

The above-named study is a multi-centre, randomized, prospective clinical trial to determine whether EC/IC (extracranial/intracranial) microsurgical arterial anastomosis is effective in prevention of first or recurrent stroke in patients with carotid distribution atherosclerotic cerebrovascular disease. This operation is well established as a technically successful procedure with low mortality morbidity. Approximately 1,000 patients from some 60 participating centres in the U.S., Canada, Western Europe and Japan will be entered during the first 3 years of the project. Criteria for entry are both (1) clinical (carotid distribution TIA, PRND, progressing stroke or completed stroke with mild deficit, occurring within past 3 months), and (2) radiological (appropriate MCA stenosis or occlusion, recognizable atherosclerotic lesions in surgically inaccessible portion of ICA, or ICA occlusion). Patients must be exempt from a number of exclusion categories and be able to provide informed consent. They are then randomly assigned to surgical or medical treatment groups, receive appropriate therapy, and are followed at 3-month intervals for 5 years or until an end-point has been reached.

The clinical aspects of the study are coordinated from the Central Office in London, Ontario, Canada and the epidemiological aspects are directed from the Methods Centre in Hamilton, Ontario. The Project Director is Dr. H.J.M. Barnett of London.

CARDIAC ABNORMALITIES AFTER BRAIN DAMAGE IN HUMANS

J.H. Feibel, University of Rochester, School of Medicine & Dentistry, Dept. of Neurology, *601 Elmwood Ave., P.O. Box 607, Rochester, New York* 14642 (R01 NS 14178-03)

The systemic, particularly cardiovascular, manifestations of acute brain injury from any cause are important causes of morbidity and mortality and may be modifiable. Many workers have shown that the autonomic response to brain damage may be important in causing the cardiovascular manifestations and we seek to continue our investigations of this relationship. By simultaneously following the metabolic, specifically catecholamine, and cardiovascular changes following acute brain damage we hope to better define the incidence, clinical presentation and importance of the systemic alterations which do occur. In this way we will better understand the mechanisms relating to these manifestations and their possible modifications by appropriate agents.

MAYO CEREBROVASCULAR CLINICAL RESEARCH CENTER

J.P. Whisnant, Mayo Foundation, Dept. of Neurology, *200 1st St. S.W., Rochester, Minnesota* 55901 (P50 NS 06663-15)

The general aims are (1) to maintain a group of clinical and laboratory investigators who can interrelate their research, (2) to investigate and resolve problems related to clinical cerebrovascular disease, (3) to study the natural history of stroke of various types by using the resources of the Rochester epidemiological facility and to determine whether various forms of management have altered the natural history, (4) to use in vitro and in vivo models of cerebral ischemia and anoxia to investigate temporal sequence of pathophysiologic changes and sequence of molecular alterations to determine the stage at which reversibility of ischemia is possible and to study what processes or agents may help to produce reversal of the ischmic process, and (5) to provide an environment for training individuals for careers of leadership in research, training, and clinical service in cerebrovascular diseases.

Clinical studies will include population studies of incidence and prevalence of stroke, mortality trends over a prolonged number of years, contribution of pre-existing cardiac disease to stroke and T.I.A. evaluation of prevalence and significance of asymptomatic carotid bruit, and evaluation of stroke in relation to mitral valve prolapse. An image analysis program will be used to study cerebral ischemia with computed tomography.

A CENTER FOR ACUTE SPINAL CORD INJURY

W.F. Collins, Yale University, School of Medicine, Dept. of Surgery, *333 Cedar St., New Haven, Connecticut* 06510 (P50 NS 10174-09)

This program is a multidisciplinary approach to the problems of spinal cord injury (SCI). Included are: An epidemiological study of spinal cord injury in Connecticut with delineation of incidence, cause, evaluation of treatment, cost comparison of treatment in an organized SCI center and community hospitals in Connecticut, and determination of when stability of neurological function occurs; studies of animal models of spinal cord injury, evaluating various treatment modalities, effects of trauma on spinal cord blood flow and metabolism, determination of spinal column stability including computer models of primate spinal column; post-traumatic alteration in blood-spinal cord barrier; the effect of biogenic amines on the resulting neurological dysfunction and ultrastructural analysis of the effect of impact trauma, the development and study of a model system in the Larvil Lamprey (Petromyzon Marinus) for study of regeneration in the central nervous system, a study of the formation of peripheral neuroma and the factors controlling its size, and study of the olfactory bulb re-establishment of central synaptic connection following injury.

SLOW INFECTION BY CONVENTIONAL/UNCONVENTIONAL VIRUSES

R.F. Marsh, University of Wisconsin, Madison Campus, School of Agriculture & Life Sciences, Dept. of Veterinary Science, *Agriculture Hall, Madison, Wisconsin* 53706 (R01 NS 14822-08)

We propose to (1) characterize the physiochemical nature of the unconventional agents producing spongiform encephalopathies in animals (scrapie and transmissible mink encephalopathy) and man (Creutzfeldt-Jakob disease), (2) to study the pathogenesis of these infections in suitable hosts, and (3) to investigate the epidemiologic interrelationships between the human and animal encephalopathies.

DESIGN OF CONVULSIVE DISORDER QUESTIONNAIRES

F. Weinfeld, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Surveys & Demographic Studies Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02239-04 OBFS)

The design and field testing of questionnaires to be used as a supplement to the NCHS Health Interview Survey (HIS). The first was designed to determine the persons with some degree of stroke, diagnosed or underdiagnosed; and hospitalization. This questionnaire was included in the 1977 HIS. A second has been designed to measure those persons with convulsive disorder and is being proposed for a future HIS. The stroke questionnaire has been submitted to NCHS and is included in their current household interview survey.

EDUCATIONAL RESOURCES IN NEUROLOGICAL EPIDEMIOLOGY

B.S. Schoenberg, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Section on Neuroepidemiology, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02307-04 ODIR)

A series of four videotapes on the principles of neuroepidemiology were produced by the Section. A two-day international conference on neuroepidemiology was held in 1977; a one-day course was held in 1977; one-day symposium was held in 1979; a 1-1/2 day course will be held in Asia in 1980; a one-week course will be held in Europe in 1981; and a one-week course is planned for Africa in 1981. A textbook entitled Neurological Epidemiology: Principles and Clinical Applications was published during 1978.

REVIEWS OF EPIDEMIOLOGIC ASPECTS OF NEUROLOGIC DISEASE

B.S. Schoenberg, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Section on Neuroepidemiology, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02299-04 ODIR)

Development of new neurologic studies requires thorough historic and methodologic reviews of prior investigations. These yield important unexplored etiologic clues that may be investigated using current technology. Major emphasis has been give to cerebrovascular disease, otitis media, inherited ataxias, Huntington's disease, and febrile seizures.

3.1206,
CLINICAL DATABANKS AS A RESOURCE OF EPIDEMIOLOGIC RESEARCH

C. Gross, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Computer Applications Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02408-02 OBFS)

Much has been written on the use of observational studies in epidemiological research. It will be necessary to apply many of the same epidemiologic techniques used in conventional observational studies to the clinical data bank. Work on determining which epidemiologic approaches are most appropriate for use with clinical data banks has begun in conjunction with the Stroke and Traumatic Coma Databank Networks (NO1-NS-8-2396, 78, NO1-NS-9-2302, 6, 7, 8, 9).

CONVULSIVE DISORDERS DATA ANALYSIS GROUP

K.B. Nelson, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Section on Cerebral Palsy & Other Motor Disorders, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02058-08 DNB)

This study examines the relationship between perinatal factors and the occurrence of seizure disorders in childhood in a large, prospectively studied population. In addition to the central question of etiology, it investigates frequency, prognosis, demographic characteristics, and a number of other aspects of these disorders. Univariate screen of maternal, obstetric, and pediatric risk factors, and demographic analysis, have been completed. File creation for multivariate analysis is now complete, and regression analyses are in progress. Selected topics of particular clinical relevance are under examination.

3.1208,
SEQUENTIAL ASPECTS OF OCCURRENCE OF SPONTANEOUS ABORTION IN FAMILY HISTORIES

A.F. Naylor, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Birth Defects & Genetic Disorders Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 01276-15 DNB)

The objective of this study has been to relate the risk of spontaneous abortion to maternal age and prior reproductive experience. Careful reconsideration of long available tabulations has shown convincingly that gravidity is a major correlate of spontaneous abortion and maternal age is of no importance. A paper making these points has been published by Fertility and Sterility.

BIBLIOGRAPHIC REFERENCES: Naylor, A.F. and Warburton, D.: Sequential aspects of spontaneous abortion. II. Collaborative Study data show that gravidity determines a very substantial rise in risk. Fertil. Steril. 31:282-286, 1979.

3.1209,
MORTALITY FROM NEUROLOGIC DISORDERS - NATIONAL AND INTERNATIONAL COMPARISONS

B.S. Schoenberg, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Section on Neuroepidemiology, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02297-04 ODIR)

Although death certificate data are limited by possible misdiagnosis, incomplete case ascertainment, errors in coding, etc., detailed morbidity information on neurologic diseases for the entire U. S. and for other countries is not available. The Section has analyzed mortality data for selected neurologic disorders by country and by county in the U. S. The overall patterns which emerge may be useful in evaluating trends over time and in formulating etiologic hypotheses.

3.1210,
TYPE-SPECIFIC STROKE MORTALITY TRENDS

H.M. Baum, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Section on Surveys & Demographic Studies, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02341-03 OBFS)

There is a need to examine stroke mortality trends by specific types of strokes. OBFS has obtained the mortality data tapes for 1968-1976, and will use these tapes to examine age-type specific stroke trends by race and sex. There are many problems inherent in such a study, but the results would be useful to health planners and administrators. Additionally, this study will be useful in generating hypotheses OBFS may be interested in examining at a later date.

DEVELOPMENT AND DESIGN OF A PILOT STUDY FOR A NATIONAL SURVEY OF EPILEPSY

D. Anderson, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Section on Disease Statistics Surveys, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02237-04 OBFS)

This pilot was initiated to develop a new and untried method of ascertaining the incidence and prevalence of epilepsy. The previously used methods have serious deficiencies and this proposal seeks to remedy them. The goal is to use pharmacies filling anti-convulsive prescriptions to lead to the physicians providing care and thus to the epileptics. By using nationwide probability sampling techniques valid estimates of the U.S. epileptic population should be made.

NATIONAL HEADACHE SURVEY

T. Chen, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Section on Surveys & Demographic Studies, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02404-02 OBFS)

The purpose of this project is to measure the extent of the problem of chronic, severe and disabling headaches, the impact of headache disorders on society, and the headache population. In addition, it is planned to examine the present usage of health care by the headache population and to identify etiological and environmental factors which may be associated with various types of headache. The survey questionnaire which includes sections on demography, medical information and history, cost, work and financial loss, etc., is currently under development. A validaton study of the questionnaire and the algorithm for identification of major types of headaches are also being designed.

GENETIC EPIDEMIOLOGY STUDIES IN MS AND OTHER MULTIFACTORIAL NEUROLOGIC DISORDERS

R. Eldridge, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Neuroepidemiology Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02167-06 ODIR)

In this project we are coupling genetic study of selected families and twin pairs with epidemiologic, immunologic, serologic and neurochemical studies of disorders due to multiple factors such as multiple sclerosis and Parkinsonism. This approach should clarify the etiology of these diseases, indicate individuals or populations at high risk and suggest mechanisms for prevention and treatment.

To date, 18 presumptive 'Multiple Sclerosis' families and 97 twin pairs with this condition have been ascertained. Over 15 twin pairs with Parkinsonism have been ascertained.

FEBRILE SEIZURES STUDY

K.B. Nelson, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Section on Cerebral Palsy and Other Motor Disorders, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02234-05 DNB)

The NINCDS Collaborative Perinatal Project has provided a large prospectively defined pediatric population, unselected for level of risk, in which to investigate the prevalence and natural history of the most common convulsive disorder of childhood, febrile seizures.

A series of papers has delineated the natural history of febrile seizures, and has identified risk factors for unfavorable outcome, and has reviewed the effect of sample selection on outcome. An NIH Consensus development meeting on Long-term Management of Children and Febrile Seizures was held. Results of the Consensus meeting, held in this year, are being prepared for publication in professional journals, and the papers are being edited for a monograph. A pilot study of cognitive and behavioral effects of anticonvulsant medication in children with febrile seizures is underway, and a major study planned which will evaluate the effects of medications and of recurrent seizures. A program announcement is planned to invite experiments on the effects of anticonvulsant agents on the developing nervous system.

EPIDEMIOLOGY OF DISABLING HEADACHE

M. Goldstein, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02449-01 OBFS)

An extensive collection and review of the published literature and reports on various aspects of epidemiology of Headache has been carried out in FY 1980. Strengths and inadequacies of the published information about prevalence, the characteristics of the afflicted population and the identification of risk factors that may be associated with both the occurrence of the headache syndrome or with its acute exacerbations were summarized and evaluated. Research approaches which can provide improved data for approaching the clinical issues of etiology, prevention and therapy were suggested. An invited paper of the review work was presented at the International Headache symposium 1980 in Florence, Italy, in March, 1980.

CLINICAL IMMUNE SURVEY OF THE LONGITUDINAL PROJECT PARTICIPANTS

W.H. Adler, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. on Aging, Clinical Immunology Section, *Baltimore, Maryland* 21224 (Z01-AG-00104-04-CPB)

The immune function of an aging human population will be evaluated to determine the age associated changes and the possible effects on the incidence and types of disease. The individuals demonstrating decreased immune function will be evaluated closely in this regard. The eventual goals will be to determine which age related diseases are associated with a decrease in immune function and therefore can be modulated by augmenting the function. The accurate assessment of function of the human population will be a major goal with the development of newer assays and the refinement of existing assays.

EPIDEMIOLOGICAL AND GENETIC STUDIES OF AMYOTROPHIC LATERAL SCLEROSIS/ PARKINSONISM DEMENTIA (ALS/PD) COMPLEX OF GUAM

C.C. Plato, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. on Aging, Human Performance Section, *Baltimore, Maryland* 21224 (Z01-AG-00028-04-CPB)

The purpose of this study is: 1) to investigate the genetic and epidemiological factors contributing to the very high incidence of Amyotrophic Lateral Sclerosis and Parkinsonism Dementia (ALS/PD) on Guam, 2) to evaluate the distribution of the various established genetic and anthropological markers among the normal Guamanian population and compare them with those of the ALS/PD patients, and 3) to ascertain the effects of immobilization due to paralysis on bone density.

ENVIRONMENTAL IMPACT ON THE ELDERLY

C.H. Patrick, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. on Aging, Epidemiology Demography & Biometry Program, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-AG-01190-02-EDBP)

An analysis of the environmental impact of pollutants generated in electric energy production was undertaken using county level data on type of facility and mortality rates of the elderly. No significant impact was found in the preliminary analysis of data from coal, oil, gas, and nuclear counties.

CATCHMENT AREA STUDY OF SENILE DEMENTIA

J. Cornoni Huntley, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. on Aging, Epidemiology Demography & Biometry Program, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-AG-04010-02-EDBP)

In conjunction with the National Institute of Mental Health, NIA is completing a study of senile dementia in an adult community population. A contract has been awarded to Yale University to survey a sample of the New Haven, Connecticut adult population for this purpose. NIA is specifically interested in defining the occurrence of senile dementia in persons 65 years of age and older. The study will consist of a household interview and a follow-up of all subjects. A questionnaire has been developed by the investigators.

3.1231,

GENERAL ANALYSIS OF NATIONAL CENTER FOR HEALTH STATISTICS DATA SYSTEMS

J. Cornoni Huntley, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. on Aging, Epidemiology Demography & Biometry Program, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 AG 02090-02-EDBP)

This contract allows the National Institute on Aging to work cooperatively with the National Center for Health Statistics in conducting analyses of appropriate data sets as the need for such analyses arises. By working in this joint manner pertinent questions can be answered more efficiently and the level of research is likely to be of higher quality than if either institute worked alone.

At the present time the research topics include: 1) the relationships between the existence of fluoride in drinking water and osteoporosis, 2) changes in incidence of stroke, 3) analysis of Family Data, 4) differences in lean body mass between the sexes and 5) mortality rates from accidents.

SENILE DEMENTIA - NATURAL HISTORY IN A NONINSTITUTIONALIZED POPULATION

J. Cornoni Huntley, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. on Aging, Epidemiology Demography & Biometry Program, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-AG-04011-02-EDBP)

Epidemiologic studies of senile dementia are needed in order to determine if the disease occurs in specific patterns by age, sex, race or other demographic and social characteristics and if such patterns would provide etiologic clues. This project will characterize persons within a community based, non-institutionalized sample who appear to have senile dementia and/or depression or to be at high risk of having these disorders. This sample will be compared with an unaffected group. Both samples will be followed over a three year period to discover risk factors and etiologic events.

MORTALITY FOLLOW-BACK SURVEY

Y.Y. Palesch, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. on Aging, Epidemiology Demography & Biometry Program, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-AG-01150-02-EDBP)

This project is designed to determine the demographic, social and economic characteristics of surviving members of cohorts relative to the deceased members. This information will be used to model and project future aged populations based on cohort characteristics. The study suggests that additional factors must be analyzed in order to determine the quantitative impacts of the environment on the health of the elderly.

SOCIOECONOMIC DETERMINANTS OF MORTALITY

S. Rosen, National Bureau of Economic Research Inc., *1050 Massachusetts Ave., Cambridge, Massachusetts* 02138 (R01 AG 00913-03)

Two large nationwide samples of individuals will be used to estimate the effects of economic, demographic, and environmental characteristics on age-specific death rates and various measures of healthiness. The project will specify and estimate a model of the determinants of morbidity and mortality of men and women near the age of 60. An important emphasis of the model will be placed on health care. we will trace out the interaction of poor health and labor force activity among people on the verge of retirement. The variables to be studied include sex, race, education, occupation and industry of work, present and historical income levels, labor force participation, state of health, family status and factors associated with place of residence, including pollution, climate, urbanization and medical services. The use of micro data allows the effects of these factors on mortality to be studied jointly and avoids aggregation and interaction difficulties inherent in macro data which have been the basis of most previous studies. In addition, the data contain information on life-cycle developments in earnings and labor market activity which have never been studied before. Multivariate probit and related methods will be used to analyze the data. The data sets to be used are the Social Security Administration CPS Exact Match tape and the Retirement History Survey tape.

3.1236,

DATA ANALYSIS IN LONGITUDINAL STUDIES OF AGING

M.A. Woodbury, Duke University, School of Medicine, Dept. of Community & Family Medicine, *Box 3711, Durham, North Carolina* 27710 (R01 AG 01023-02)

The objective of analyzing and characterizing the multivariate and dynamic states of individuals as they age is being pursued. Data from the first Duke Longitudinal Study have been screened and a set relatively free from missing data has been selected. Data absent due to the death of individuals is not considered to be missing in this selection process. In addition, attention has been paid to changes in the definition of variables in selecting variables for the first analysis.

Two studies have been initiated to date. The first is concerned with the dynamics of risk variables known to contribute to mortality from vascular diseases. The variables used in this study are logged values of the physiological variables: diastolic blood pressure, pulse pressure, serum cholesterol and the performance component of the Wechsler Intelligence Tests. The calculations for this study are almost complete and the results, in part, assimilated. The second study concerns the mortality due to vascular disease as predicted by the risk variables whose dynamics were evaluated in the first study. Manuscripts describing the results of the analyses are in prepartion.

SPECIAL INITIATIVES RELATED TO DEMENTIA

R. Katzman, Yeshiva University, Bronx Campus, Albert Einstein School of Medicine, Dept. of Neurology, *1300 Morris Park Ave., Bronx, New York* 10461 (R21 AG 01184-03)

Senile dementia of the Alzheimer type (SDAT), the major cause of dementia among the elderly, is a growing health problem. Although much has been learned about the pathophysiology of this disease, little is known about etiological factors. We propose to seek information about specific genetic, environmental, and metabolic risk factors by carrying out a cross-cultural case control study of SDAT. We will utilize an epidemiological interview together with studies of serum haptoglobins as linked genetic markers; immunological changes manifested by lymphocyte responses and serum immunoglobulins; serum antibodies to choline acetyltransferase, and parathormone status. One aspect of the social impact of SDAT will be studied by investigating techniques adopted by families for coping with an afflicted family member.

AGING AND HETEROGENEITY IN MORTALITY RISKS

K.M. Weiss, University of Texas, Health Science Center at Houston, Graduate School of Biomedical Sciences, Center for Demographic Population Genetics, *P.O. Box 20334, Houston, Texas* 77025 (R01 AG 01028-03)

This study will examine risk heterogeneity in age patterns of mortality by cause at various levels of population. Risk of death from major causes of mortality, by age, will be parametrically described, taking account of competing causes. This will be related to the theory of human biological aging. Risk-rate parameters will be characterized statistically, including their sample variances, their geographic and temporal clustering, and their inter-cause correlations. This will first be done on subdivisions of nations using data from Chile and Texas to look for more local effects and variations. Finally, risk functions will be estimated for the Mexican-Americans of Laredo, Texas. Here risk assessment and studies of risk heterogeneity will be done on genealogical data so as to examine the genetics of longevity as they relate to specific causes of death and the age at which they occur, and cluster, in families.

CASE-CONTROL STUDY OF PRESENILE AND SENILE DEMENTIA

A. Heyman, Duke University, School of Medicine, Dept. of Medicine, *Box 3711, Durham, North Carolina* 27710 (R21 AG 01186-03)

The present proposal is a collaborative case-control study of a small cohort of patients diagnosed as having, on the basis of carefully established clinical criteria, presenile or senile dementia of the Alzheimer's type. Information will be obtained regarding factors possibly related to the development of this illness from these patients and from matched control subjects by means of a structured epidemiologic interview, by analyses of serum and cerebrospinal fluid for viral antibodies and for increased concentrations of aluminum and other metallic ions and by detailed family history searching for evidence of genetic defects. The natural history of the disorder and the correlation between the progressive mental changes, the electroencephalographic abnormalities and the changes in computer tomography of the brain will also be studied.

DEPRESSION, INFORMATION PROCESSING AND AGE

P.M. Lewinsohn, Oregon State Higher Education System, University of Oregon, School of Liberal Arts, Dept. of Psychology, *1472 Kincaid St., Eugene, Oregon* 97401 (R21 AG 01449-02)

Two separate projects are proposed. Project 1 ('Epidemiology of Depression in the Elderly') is a longitudinal prospective study of a representative sample of 900 elderly persons. Subjects are assessed on a wide range of measures at point of entry into the study. They will be followed for two years during which time their depression level will be monitored on a monthly basis. Clinical assessments will be done on subjects who become depressed. Four types of hypotheses will be tested: 1) What are the distinguishing characteristics of elderly persons who become depressed? 2) What are the distinguishing characteristics of elderly persons who are depressed? 3) What are the distinguishing characteristics of elderly persons who are depressed and who recover? 4) What are the distinguishing characteristics of elderly persons who have a history of having been depressed earlier in life?

Project 2 has three objectives: 1) To adapt an existing conceptualization of the key ability factors underlying cognitive performance to the study of the aging. 2) To use the measurement devices constructed as per objective 1 to evaluate the effects of cardiovascular conditioning on the cognitive behavior of elderly depressed and elderly non-depressed Ss. 3) The measurement devices will be used to assess cognitive functioning as a function of age.

EPIDEMIOLOGIC STUDY OF ALZHEIMER'S DISEASE

L.M. Schuman, University of Minnesota, Minneapolis Campus, School of Public Health, Dept. of Epidemiology, *1325 Mayo Memorial, Minneapolis, Minnesota* 55455 (R01 AG 01529-02)

OBJECTIVES: To explore by a case-control study factors of possible etiologic significance to the occurrence of Alzheimer's disease. Variables relevant to viral, genetic and immunological hypotheses will be explored, and data on occupational and environmental exposures, drug use, psychological stress, smoking and alcohol consumption also will be collected.

METHODS: A total of 100 cases of Alzheimer's disease will be identified from patients at the Veteran's Administration Medical Center and the University of Minnesota Medical Center, both in Minneapolis. For each case a hospital control matched for age, sex, race and admission date, and a neighborhood control, matched for age, sex and race, will be selected. For each subject as informant will be identified and interviewed with a structured questionnaire about variables and data mentioned above in 'Objectives'. Data from existing records will also be abstracted and analyzed.

3.1242,

ACCURACY OF DEATH CERTIFICATE AGES FOR THE EXTREME AGED

I. Rosenwaike, University of Pennsylvania, School of Medicine, Dept. of Research Medicine, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174 (R01 AG 01550-02)

This is a matched records study that will attempt to verify the accuracy of the reporting of age on the death certificate among persons in the extreme aged population. A sample of about four thousand decedents around 1970 will be selected from death certificates filed in the states of Pennsylvania and New Jersey. These records will be linked with the listing in the 1900 census, conducted when the decedent presumably was a youth or young adult. The motive to exaggerate age attributed to the elderly would not have been present at this early period.

Effort will be made to correct age on the death certificate on the basis of the 1900 census records. The 'adjusted' distribution of deaths by age around 1970 so derived, will permit the computation of corrected death rates and life tables. These data may then furnish a basis for improving mortality statistics at older ages, and for evaluating the quality of census data. In addition, they may provide a better appreciation of the basic causes of the anomaly of the cross-over of nonwhite mortality to lower levels than white mortality at the upper age range.

3.1243,

AGING AMONG THE MENNONITES OF KANSAS AND NEBRASKA

M.H. Crawford, University of Kansas, Lawrence Campus, School of Liberal Arts & Sciences, Dept. of Anthropology, *112 Bailey Hall, Lawrence, Kansas* 66045 (P01 AG 01646-02)

The purpose of the research project is to examine the interaction of genetic and environmental factors

which affect aging and longevity. A multidisciplinary approach has been adopted to deal with the various biological and environmental components which affect the aging process. The disciplines examining the components of aging are biological anthropology and genetics, medicine, physiology, cultural anthropology, sociology, and psychology. In addition to the partitioning of genetic and environmental factors, the effects of inbreeding on longevity will be examined, a method for determining biological vs chronological aging will be tested, historic trends in the life expectancy of the study population will be analyzed, cultural normative values and structures will be compared with the actual statistic patterns observed, and a theory of subjective competence will be developed regarding social aging processes. In addition, patterns of longevity and mortality in the historical Alexanderwohl congregation will be determined through the analysis of church and historical records. Records date back to the Seventeenth Century and document the migration of the Alexanderwohl community during their sojourns from Prussia to Russia to Kansas.

PERSONAL PATTERNS PREDICTIVE OF DISEASE OR DEATH

C.B. Thomas, Johns Hopkins University, School of Medicine, Dept. of Medicine, *725 N. Wolfe St., Baltimore, Maryland* 21205 (R01 AG 01760-02)

Prospective studies carried out by the Precursors Study suggest the existence of psychological factors which precede the clinical appearance of premature disease or death by many years. We obtained an extensive, unique data base (psychological, psychosocial, physiological, medical and familial) on a cohort of 1,337 medical students and have followed them prospectively for 18 to 32 years. Now for the most part between the ages of 41 and 60, 68 of them have died, and more than 200 are living with serious disorders, including hypertension, coronary heart disease, cancer and mental illness.

It is our aim: a. to study the enlarging disorder group in detail in an attempt to substantiate the youthful psychological characteristics we have already found in this cohort which appear to be potential predictors of several disease states; b. to search prospectively for new potential predictors within the psychological and behavorial data; c. to determine whether special clusters of predictive variables appear to be associated with particular types of disease; and d. to bring together the substance of the Precursors Study's findings to date.

BIBLIOGRAPHIC REFERENCES: Betz BJ, Thomas CB: Individual temperament as a predictor of health or premature disease. Hopkins Med J 144: 81-89, 1979. Thomas CB, Santora PB, Shaffer JW: Health of physicians in midlife in relation to use of alcohol. Hopkins Med J 146: 1-10, 1980.

3.1245,
DETERMINANTS OF AGING AMONG SEVENTH-DAY ADVENTISTS

J.W. Kuzma, Loma Linda University, School of Health, Dept. of Biostatistics & Epidemiology, *Loma Linda, California* 92354 (R01 AG 01582-02)

Seventh-day Adventists are persons who neither drink nor smoke; over 40% are vegetarians. Their age distribution shows a significant proportion of older persons. In 1958, a longitudinal study of California Adventists was mounted to investigate the association of life habits with mortality and life expectancy. Results showed them to have a longer life expectancy than the general population and lower mortality rates for many chronic diseases. Since 1974, a larger group of Adventists has been studied to determine morbidity from major disease and to learn which factors in their lifestyle are associated with an extended longevity and reduced disease risk. The two separate studies have some 20,000 common enrollees but their records have not yet been linked.

Objectives of the research are fourfold; 1) to ascertain the vital status of persons originally enrolled and link their records with current enrollees, thus providing a 20-year mortalitiy followup; 2) to analyze long-term results in terms of the epidemiological correlates of aging; 3) to compare mortality data of the Adventist population with a comparable population from the general public; and 4) to learn whether Adventist's extended mortality is due to selective factors or results from the unique, if somewhat variable practices of group.

The methodology involves a computerized probability model to link data files of the two studies, along with trained field workers tracing church membership records.

Investigation into the longevity and quality of life of the oldest members of a long-lived group seems to be appropriate at a time of steady increase in the number of elderly persons in the general population.

MARITAL, SEXUAL AND SOCIAL FACTORS IN AGING

C. Martin, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. on Aging, Human Performance Section, *Baltimore, Maryland* 21224 (Z01 AG 00018-14 CPB)

Systematic data concerning sexual, marital and social experience were obtained by structured interviews with males taking part in the Baltimore Longitudinal Study of Aging. In the course of the year, subjects aged 79 and younger at interview with a positive diagnosis of coronary heart disease (CHD) prior to July 1, 1979, were closely matched on age at interview to subjects negative for CHD. In over one hundred comparisons between CHD subjects and their controls, a remarkable correspondence between them was found in regard to wide range of personal and experiential attributes pertaining to marriage and sexual activity. In sum, present findings clearly suggest that these phenomena play no role in the etiology of CHD.

INVESTIGATIONS OF OSTEOARTHRITIS AND BONE LOSS

C.C. Plato, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. on Aging, Human Performance Section, *Baltimore, Maryland* 21224 (Z01-AG-00022-04-CPB)

Osteoarthritis and bone loss are the two principal age related changes of the human skeleton. Even though these changes are considered inherent to aging, they may result in incapacitating ailments. The advanced cases of osteoarthritis (degenerative joint disease) produce severe restriction of movement associated with pain. Advanced bone loss may result in osteoporosis and frequent bone fractures. Most prominent are vertebral compression fractures and fractures of the femoral neck.

This project deals with the epidemiological, genetic and longitudinal aspects of osteoarthritis and bone loss among (1) the participants of the Baltimore Longitudinal Study, (2) in a sample of normal Guamanians (Chamorras), and (d) among patients afflicted with amyotrophic Lateral Sclerosis/Parkinsonism Dementia Complex of Guam. (4) Guamanian children of ages 7-17 who lived on Guam during periods of severe nutritional deprivation.

PROSPECTIVE STUDY OF NUTRITION IN THE ELDERLY

J.S. Goodwin, University of New Mexico, School of Medicine, Dept. of Medicine, *University Hill N.E., Albuquerque, New Mexico* 87131 (R01 AG 02049-02)

The purpose of this study is to examine the effects of subclinical malnutrition on the physical health and life expectancy in 300 elderly people over a five year period. The nutritional status of these elderly individuals (65 years and older) is evaluated by yearly clinical exams, a three day diet history, and biochemical analysis of blood samples for total protein, albumin, transferrin, iron, total iron binding capacity, vitamins A, C, D, E, B6, B12, folate, riboflavin, thiamine, cholesterol, HDL cholesterol, triglycerides, copper and zinc. The results of these individual assessments will then be used to determine whether poor nutritional status predisposes subjects to increased morbidity and mortality during the five year follow-up period. These elderly individuals are also being evaluated immunologically with skin tests and in vitro mitogen responses to determine whether depressed immune

function correlates with subclinical malnutrition in this population.

EPIDEMIOLOGY OF OSTEOPOROSIS IN A JAPANESE POPULATION

R.D. Wasnich, Kuakini Medical Center, *347 N. Kuakini St., Honolulu, Hawaii* 96817 (R01 AG 02483-01)

The study is designed for longitudinal investigation of bone mineral loss and non-violent fractures in a homogeneous Japanese population in Hawaii, in conjunction with the Honolulu Heart Study and the Japan-Hawaii Cancer Study. This unique, well-studied population is one of exceptional stability and longevity, and also possesses unique social and cultural differences with regard to aging. Bone mineral loss will be assessed over a five-year period using photon absorptiometry, and non-violent fractures will be monitored. Loss of bone mineral will be correlated with multiple personal, social, and dietary characteristics, with special emphasis upon physical activity levels following menopause and retirement. Environmental and genetic factors will be studied by comparison of results with similar studies of Caucasians on the U.S. mainland. Osteoporotic subjects developing non-violent fractures will be compared to osteoporotic subject without fractures in an attempt to define pathologic versus physiologic bone mineral loss. This comparison will include extensive histopathologic examination at autopsy. A final aim is to identify a possible subgroup in a rapid, active stage of bone mineral loss who could prove valuable in a further study of the pathophysiologic mechanisms involved in osteoporosis.

3.1253,

SLEEP AND ITS DISORDERS IN THE FAMILY

W.C. Dement, Stanford University, School of Medicine, Dept. of Psychiatry & Behavioral Sciences, *300 Pasteur Dr., Stanford, California* 94305 (P01 AG 02504-01)

This is a program project proposal. It requests support for nine individual projects. Each project will address some aspect of sleep and sleep disorders as a function of the aging process. Two large projects involving clinical sleep disorders form the core of the program. The first includes a precise, comprehensive assessment of the prevalence of sleep-wake disorders in discrete populations of elderly individuals. The core project involves a broad-based longitudinal assessment of elderly persons with sleep apnea syndromes and matched control subjects. The longitudinal study will evaluate mortality, morbidity, cardiovascular-respiratory function, cognition, behavioral function, and daytime alertness. Essential to the efficient progress of the two core projects are the installation and refinement of a sleep disorders information system and a series of microcomputer-based ammbulatory monitors. Another clinical project involves two key issues in hypnotic safety and efficacy in elderly patients; the effect of sleeping pills in individuals with sleep apnea, and the effect of sleeping pills on daytime alertness. Four additional projects will address basic research issues concerning sleep and aging. Circadian rhythms and aging will be evaluated using life span recordings of sleep-wake and activity-inactivity in mice. Nocturnal determinants of daytime alertness in elderly humans will be evaluated in a series of sleep restriction, sleep loss, and napping studies. The precise relationship of respiratory function during sleep to aging will be evaluated using sophisticated invasive procedures in cats. Finally, the fourth project will focus on neurochemical processes during sleep in the aging brain, with in vivo studies of young and old cats and dogs. A planning group, including epidemiologists, statisticians, gerontologists, and others will direct the project and integrate the research findings.

THE U.S. MORTALITY DECLINE - EVIDENCE FROM CENSUS DATA

E.M. Crimmins, California Inst. of Technology, Graduate School, Dept. of Humanities & Social Sciences, *1201 E. California Blvd., Pasadena, California* 91109 (R01 AG 02699-01)

The purpose of the proposed research is to estimate levels and trends in U.S. mortality in the last half of the nineteenth century. In addition to estimating levels and trends at a national level the proposed project will estimate mortality differentials for regions of the country, rural and urban areas, and nativity groups. The project will also examine the determinants of mortality levels and change during this period. Data on nutritional levels and the provision of public health provisions will be related to mortality conditions. Mortality data available in the federal census will be used in this research. This research will add to current knowledge on the demographic transition by clarifying the American experience and by testing a number of theories of causation of the decline in mortality in the now developed world.

3.1255,

INTERNATIONAL DATA ON HEALTH RESEARCH ON THE ELDERLY

D.M. Macfadyen, World Health Org., *Copenhagen, Denmark* (R13 AG 02704-01)

The World Health Organization (WHO) through its Care of the Elderly Program will collect, review, and evaluate data on the behavioral, societal, economic, and organic aspects of aging in its member nations including the developing countries through industrial societies. The data collected will be information on various programs relating to health status, self-care, family care, and health education. The National Institute on Aging (NIA) is interested in developing the health and demographic data with the WHO. A conference composed of a small work group, international in membership, is to convene in December 1980 to review the epidemiological aspects of increased survivorship in order to guide preparations for the U.S. World Assembly on the Elderly to be held in 1982. Recognized experts in the field of health and social care for the elderly will be commissioned to prepare documents for the conference. A report will be produced including recommendations for social policy life enhancement of the elderly research, education, and technical cooperation among developing and developed countries.

3.1256,

DEPRESSION AND PARKINSON DISEASE - A MODEL IN AGING

R. Mayeux, Columbia University, College of Physicians & Surgeons, Dept. of Neurology, *630 W. 168th St., New York, New York* 10032 (R23 AG 02802-01)

The goal of this investigation is to evaluate biological factors in the depression of Parkinson Disease (PD) as a model of depression in the elderly. The prevalence and severity of depression will be determined and the associated intellectual changes will be documented. The relationship between the severity of PD, independence in daily activities, and depression will be analyzed. Metabolites of serotonin and norepinephrine in cerebrospinal fluid and urine will be studied. The functional integrity of the hypothalamus will be examined by provocative methods of stimulation and inhibition of anterior pituitary hormones, and by examining responses to thermal stress.

The long term objective of this study is to determine the role of the biogenic amines, serotonin and norepinephrine, in depression in PD, and to determine the relationship of degenerative changes within the hypothalamus in PD to depression. A longitudinal, prospective investigation is planned over three years. Hospitalization will be required in the General Clinical Research Center for purposes of withdrawing medication during the biochemical studies. The endeavor will cross several disciplines including Psychiatry, Neuropsychology, Neurochemistry, Neuroendocrinology and Neurology.

Depression and dementia constitute two major clinical features of PD that are poorly understood. These two disorders are also major health problems for the aged, and PD may serve as a model disease for the study of depression. Metabolic studies of primary depressive disorders implicate disturbances within the monoamine and hypothalamic-peptide systems, but are lacking in pathological verification. On the other hand, pathological changes in hypothalamus and loss of monoamines in PD are recognized, however, clinicopathological correlation is lacking. Should a relationship exist, it would broaden our understanding of the pathophysiological mechanisms underlying depression not only in PD but aging as well.

3.1257,

ANTECEDENTS OF PSYCHOLOGICAL HEALTH STATUS IN THE AGED

J.J. Conley, Wesleyan University, School of Liberal Arts & Sciences, Dept. of Psychology, *Middletown, Connecticut* 06457 (R23 AG 02837-01)

Psychological health status (emotional disorders, alcohol abuse, and life satisfaction) in the aged is assessed in a panel of subjects who have been under study for forty-five years. The antecedents of these aspects of psychological health status of the aged were measured in 1935-8 and 1954-5. These antecedents included familial, marital, occupational, health, and attitudinal factors as well as personality traits. The first data collection was undertaken by E. Lowell Kelly and involved the recruitment of 300 engaged couples for a longterm study of marital compatibility. Of these 600 subjects, seventy-four percent responded in the second data collection in the 1950's. As of June, 1980, 342 (fifty-seven percent) of the original subjects have responded in a third data collection. Another 109 of the original subjects are known to be deceased. The target number of responses is 400. The relationships of the antecedent variables to the three components of psychological health status in the aged and the interrelationships of the antecedents are studied by the statistical technique of path analysis. This analysis will permit causal inferences about psychological problems of the elderly and permit estimates of the relative contributions of early versus later determinants of psychological disturbances in older persons. The effects of biases in the original sample toward over-representations of better educated and more intelligent subjects and attrition biases toward marital stability, low geographical mobility and longevity will be assessed by means of stratified data analyses. The confirmed models involving antecedents and outcomes will permit estimates of the effectiveness of treatment and prevention efforts on the psychological health status of the aged. The relationships of physical and psychological health problems over time can be determined since physical symptom checklists and information from the research partner (fiance, later spouse) on physical health were gathered in all three data collections. The linkage of psychological stress and cardiovascular diseases and the social predictors of early senility can be assessed longitudinally with this data set.

EPIDEMIOLOGY OF FRACTURES IN AGING WOMEN

N.S. Weiss, Fred Hutchinson Cancer Research Center, *1124 Columbia St., Seattle, Washington* 98104 (R01 AG 01764-03)

A case-control study is being proposed to determine to what extent exogenous estrogens protect against fractures among menopausal women. All women who (a) sustained a fracture of a hip or forearm during the interval April 1977-March 1979, (b) were 50-74 years of age and residents of King County, Washington, and (c) were treated by one of several dozen orthopedic surgeons participating in the study will be identified. They will be interviewed concerning use of estrogen preparations and related matters, and their answers compared to those of a random sample of women in the community.

3.1261,

DEVELOPMENT OF GLOSSARY OF EPIDEMIOLOGIC TERMS

J. Amsel, University of Pennsylvania, School of Medicine, Dept. of Research Medicine, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174 (R01 LM 03531-02)

The proposed research will utilize regional and international committees to construct a cooperative glossary of epidemiologic terms, sponsored by the International Epidemiologic Association. This glossary is designed to unify terminology currently being used in the field, and to provide a comprehensive compendium of definitions of epidemiologic terms for reference by workers in the field and in related fields. At present, the collection of terms being used in the field has proliferated to the point that a number of terms are frequently used for a single concept, and vice versa. The glossary will provide a forum for decision-making by a representative body of individuals in the field. The initial proposed collection and grouping of terms to be defined will be carried out by the investigators, and revisions will be made by a committee composed of members from North American institutions. Definitions of terms will be initially drafted by the investigators and will be revised by the North American committee. The final draft of the North American committee will then be submitted to an international committee of International Epidemiological Association regional representatives, who will review the definitions. Those for which a majority of regional representatives suggest a change will be revised, and a vote taken on suggested definitions. Checks will then be carried out by the prinicpal investigators to ensure that no internal inconsistencies among definitions exists. An index will then be prepared. The resulting glossary will represent a first edition, and it is expected that periodic updatings will occur under the auspices of the IEA.

3.1262,

MONOGRAPH - INFECTIOUS DISEASE - SIMULATION OF EPIDEMICS

E. Ackerman, University of Minnesota, Minneapolis Campus, School of Medicine, Dept. of Laboratory Medicine & Pathology, *1305 Mayo, Minneapolis, Minnesota* 55455 (R01 LM 03582-01)

A monograph, 'Infectious Disease: Simulation and Vaccination Strategies,' is proposed. This reorganization would make available in single document the results of studies by the investigators, extending over two decades. This information previously has been published in a variety of journals; the spread of the information makes it inconvenient for use in the teaching of the epidemiology of infectious diseases. The monograph should provide a valuable library aid as well as enabling other investigators to generate simulation routines of a similar or related nature.

An attempt will be made to divide each chapter into two parts. One would be aimed at an audience similar to the readership of the American Journal of Epidemiology. The other part of each chapter would discuss simulation algorithms and techniques in greater depth.

This monograph should be useful to research epidemiologists interested in infectious diseases, to public health officers concerned with vaccination strategies, to students in epidemiology, and to computer scientists and medical informatics specialists interested in applications of Monte Carlo simulation techniques. The primary consumers of such a monograph would be biomedical libraries. A number of additional copies might be purchased by individual research workers and University professors. Current estimate of number of copies desired is about 1,000.

3.1263,

COST EFFECTIVE METHODS FOR COLLECTING HEALTH DATA

S. Sudman, University of Illinois, Urbana Champaign Campus, Survey Research Lab., *414 David Kinley Hall, Urbana, Illinois* 61801 (R01 HS 03843-01A1)

The proposed study will assess the cost-effectiveness of mixed mode methods for collecting health data by combining diary mail-in procedures, which yield higher quality data, with telephone interviews, which are less expensive. The objective of the research is to determine how the cost of diary panel procedures could be reduced without unduly compromising the quality of the data obtained. The design calls for three rotating panels of 400 households each. At the conclusion of an initial interview, each respondent will be asked to maintain a monthly or bimonthly diary of household health events for a four-month period. Any respondent who fails to return a monthly diary will be interviewed by telephone. One year later each household will be asked to continue in the panel for a period of one, two, or four months. The following experimental treatments will be tested utilizing a 2 to the second power x 3 x 4 factorial design: 1) initial face-to-face vs. telephone interviews; 2) compensation for a completed diary or telephone interview vs. compensation contingent on completion of a diary; 4) one-month diary forms vs. two-month diary forms; 5) telephone vs. monthly mail vs. no scheduled contact with households.

DRUG PRESCRIBING & EVALUATIONS BY PHARMACISTS IN SNFS

J.F. Thompson, University of Southern California, School of Pharmacy, Dept. of Pharmacy, *2025 Zonal Ave., Los Angeles, California* 90033 (R18 HS 03898-01)

To investigate two different interventions with the objective of improving the quality and economy of drug prescribing in nursing homes, a randomized control-group, pretest, post-test design will be implemented. Participating patients in various skilled nursing facilities (SNFs) will be randomly assigned in each SNF to three groups. Group I will receive drug prescribing by pharmacists with physicians responsible for the medical diagnoses and monthly physical reassessment of the patients. Group II will involve comprehensive drug therapy evaluations written monthly by pharmacists which can be utilized by the physician for prescribing decisions. Group III will be the control group receiving the normal physician prescribing and pharmacist monthly review in compliance with current SNF regulations. Process and outcome measures will be utilized to compare the ability of these experimental treatments to reduce the incidence of inappropriate therapy, reduce the incidence of adverse drug reactions, reduce the use of unnecessarily costly drug products and improve other factors related to the quality and economy of the patients care and drug therapy. Various descriptive and analytical statistical procedures will be used as appropriate to examine the data and results, including cross tabulations and analysis of variance.

EVALUATION STUDY OF AN ALTERNATIVE BIRTHING CENTER

G. Baruffi, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Maternal & Child Health, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 HS 03762-02)

Over the past few years, increasing numbers of women have elected to deliver outside the hospital in maternity centers or at home. The objective of this study is to evaluate the physical safety of an 'out-of-hospital' maternity center. Two questions are addressed by this epidemiological prospective non-concurrent study: 1) Do maternal and neonatal outcomes of two populations comparable on sociodemographic and medical-obstetric risk differ in two institutions with different approaches to maternity care? 2) Does the process of transfer from one institution to another involve increases risk to sick pregnant women and newborns?

The study populations, selected from Booth Maternity Center and Thomas Jefferson University Hospital, both located in Philadelphia, Pennsylvania, will be matched by distribution for the investigation of the first question and by pair for the investigation of the second. Matching variables will be: race, maternal age, education, gravidity, and previous pregnancy loss. Pregnancy outcomes process of care, medical-obstetric risk and sociodemographic characteristics will be analyzed by univariate and multivariate statistical techniques.

AN ANALYSIS OF DATA FROM THE LOUISVILLE CHILDHOOD LEAD POISONING CONTROL PROGRAM

Unknown, Louisville & Jefferson City Dept. of Public Health, *400 E. Gray St., Box 1704, Louisville, Kentucky* 40201 (H-2550RG)

This is a continuation of a joint HUD/HEW demonstration project underway since 1976. In 1978 the tasks of establishing an operating model program were completed. The data from files of the 14,000 children screened since 1974 was coded and entered onto a computer data base. In this fiscal year an analysis of this data base will be continued to determine those characteristics (child, housing, air, plumbing) associated with higher lead-in-blood levels and whether long-range effects of these elevated levels are detectable.

SOCIAL SUPPORT FOR MEDIATING THE EFFECTS OF OCCUPATIONAL STRESS ON THE HEALTH OF INDUSTRIAL WORKERS

J.A. Wells, Duke University, Graduate School, *Durham, North Carolina* 27706 (91-37-76-53)

The effects of various types and sources of social support on the relationship between job-related psy-

chosocial stress and worker health are explored in this study. Since interpersonal relations are perhaps the most tractable aspect of the work environment, the results of this research will have direct policy implications for the improvement of worker health, a primary determinant of the quality of work. The results will also contribute to building an empirically based theory of social support. The data include: (1) Questionnaire measure of perceived stress, social support, and health collected in a large plant manufacturing rubber, tires, plastics, and chemicals; (2) physical examination measures gathered on a subsample of workers by the National Institute of Occupational Safety and Health (NIOSH) and OHSG; and (3) objective job-stress ratings by a panel of judges including members of the union, plant management, and members of the research team familiar with the plant.

THE HEALTH EFFECTS OF AIR POLLUTION ABATEMENT

L.B. Lave, Carnegie Mellon University, Graduate School of Industrial Admin., Dept. of Economics, *Frew Ave. & Margaret Morrison, Pittsburgh, Pennsylvania* 15213 (R806365-01)

An epidemiological investigation of the effect of air pollution on mortality rates for the general population is the focus of this study; it seeks to isolate the qualitative and quantitative association between particular air pollutants and various mortality rates, controlling for other factors hypothesized to affect mortality. Statistical analysis of more than 100 US cities from 1960 through 1974 will be the basic method. Previous analyses will be replicated with the new data set and attempts will be made to investigate defects in earlier analyses. If forecasts from previously estimated models fail to predict mortality rates in cities or if there is evidence of misspecification of the relationship, additional functions will be investigated. Attempts will be made to isolate the effects of individual pollutants and to control for smoking habits. Finally, the best estimates of the effect of air pollution on mortality will be translated into estimates of the benefits of air pollution abatement.

HEALTH EFFECTS OF AIR POLLUTION IN THE TEXAS GULF COAST AREA

P.A. Buffler, University of Texas, Health Science Center at Houston, School of Public Health, Dept. of Epidemiology, *6515 Freeman, Houston, Texas* 77025 (R807108-01)

In order to assess the biomedical consequences of exposure to air pollution in the Texas Gulf Coast Area, three epidemiologic studies are proposed: (1) a two-phase study of environmental influences on lung cancer production in Harris County, where the city of Houston is located; (2) a longitudinal assessment of the degree to which daily variation in air pollution concentrations influences daily symptomatology and lung function in asthmatics; and (3) a longitudinal assessment of the degree to which air pollution concentrations shortly preceding and during exercise influence performance, physiology, and symptomatoloty in vigorously exercising healthy people.

This group of studies has been selected to achieve balance in four respects: 1) the studies will assess the influence of short-term, daily and chronic exposures, 2) the studies will consider a spectrum of health outcomes, 3) the studies consider variables ranging from those which could reflect an existing air pollution effect whose biological significance is difficult to quantify to those which may be difficult to associate with pollution exposure, but whose biological significance is unequivocal, and 4) all the studies are designed to address specific biomedical environmental aspects of the Texas Gulf Coast Area and to yield results which can be directly compared to other studies in the Southern California Area.

These investigations will be collaborative efforts of the University of Texas School of Public Health and the Population Studies Division of the Environmental Protection Agency. The study design specification for each investigation will be determined collaboratively during the first months of each study.

COOPERATIVE AGREEMENT FOR EPIDEMIOLOGY RESEARCH CENTER

E.P. Radford, University of Pittsburgh, Graduate School of Public Health, Dept. of Epidemiology, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (R806815-01)

By a cooperative research center agreement between of the EPA and the University of Pittsburgh, an Environmental Epidemiology Center would be established at the University's Graduate School of Public Health. Its primary goals would be to: (1) bring together a wide range of school, university, community, regional, national, and even international resources to plan and perform research in the field of environmental epidemiology and contributory and related fields; (2) provide specialized assistance to the EPA; (3) provide means for scientists in these fields from outside the university to contribute to Center research, service, and educational activities; and (4) provide advanced graduate and post-graduate training in these fields. An executive committee, comprised of Dr. Edward P. Radford, Director and Professor of Epidemiology, Dr. Philip E. Enterline, Associate Director and Program Coordinator for Biometry, Program Coordinators for Environmental Epidemiology of Chronic Disease, Environmental Toxicology, Air and Water Pollutant Effects, and Environmental Radiation Effects (Drs. Lewis H. Kuller, Yves C.E. Alarie, Julian B. Andelman, and Neil Wald, respectively), Dean and Professor of Epidemiology Herschel E. Griffin, and Directors of EPA Health Effects Research Laboratories, would govern the Center with the assistance of a National Advisory Board having EPA, Center, and 'external' representation. A variety of mechanisms having optimal flexibility to respond to ever-changing needs and circumstances would be used to address needs of the EPA and field of environmental epidemiology and assistance needs of the EPA. In addition to research and service activities, Center Fellows, Visiting Scholars, EPA Visitors/Exchange, and Symposium Series Programs would be established. The Center would also provide graduate- and post-graduate-level training, and perhaps new courses and educational programs in environmental epidemiology would be established through the Center and School.

FATAL ACCIDENT REPORTING SYSTEM (FARS)

P.W. Haseltine, State Office of Highway Safety Planning, *7150 Harris Dr., General Office Bldg., Lansing, Michigan* 48913

Since 1972, the National Highway Traffic Safety Administration (NHTSA) with the cooperatioh of the States has been developing the Fatal Accident Reporting System (FARS). The FARS is a national computerized data collection system which contains reports of current data on all motor vehicle traffic accidents in which there is a fatality. The FARS definition of a fatality is one which occurs within thirty (30) days of a motor vehicle traffic accident and as a result of the accident. The FARS is a primary tool which can be used by the NHTSA, the States, and the highway safety community to quantify the national and State fatal accident picture, to identify problem areas, to evaluate highway safety countermeasure programs, and to enhance operation at both State and Federal levels. The FARS data is used to produce official NHTSA fatality statistics and reports to make the public aware of changing trends in highway fatalities. Special data on particular accidents such as airbag accidents, air brake truck accidents, etc. can be helpful to the DOT in making sensitive policy decisions regarding implementation or evaluation of Federal Motor Vehicle Safety Standards. Included in the system are data describing the accident, vehicles, drivers, occupants and non-occupants. Primarily, data elements are extracted from the police officer's traffic accident report and from special supplementary reports which may be placed in the State's police report file. In addition, data is extracted as needed from other sources which include but are not limited to the driver license files, vehicle registration files, death certificates, coroner's reports, hospital records, autopsy reports, Vital Statistics files, Emergency Medical Service records, and State Highway Department records.

DEVELOPMENT AND EVALUATION OF AN ENVIRONMENTAL DATA ANALYSIS SYSTEM

L. Milask, Sigma Data Computing Corp., *12730 Twinbrook Pkwy., Rockville, Maryland* 20852 (79-0655)

OBJECTIVE: The objective of the IAG is to provide for collaboration in the development and application of the UPGRADE System to support analysis in the area of environmental health.

APPROACH: Databases dealing with such environmental health areas as populations at risk to air polluton, morbidity and mortality rates, and/or health care utilization will be investigated and appropriate variables added to existing databases. These data will be analyzed using the UPGRADE System and reports prepared.

PROGRESS: Investigation of databases has begun. Enhancements to the UPGRADE/EXTRACT System to allow for increased data capabilities are underway. Information on the SMSA level is being collected and morbidity rates are being calculated in preparation for a new database. New release 4.0 has been com-

pleted and is in operation. User's manual will be available by January 1980.

THE EFFECTS OF OXIDANT AIR POLLUTANTS ON HUMAN RESISTANCE TO VIRAL INFECTION

Unknown, University of North Carolina, Chapel Hill Campus, Graduate School, *Chapel Hill, North Carolina* 27514 (68-02-3403)

Epidemiologic and animal studies show that oxidant air pollutants contribute to an increase in the number and/or severity of respiratory tract infections in man are caused by respiratory viruses, and therefore, the effect of an air pollutant on the host-virus interaction should be examined. The objective of this project is to determine in human subjects whether the host response to respiratory viral infections is decreased and to define the mechanisms of altered resistance related to the air pollutant exposure. The ultimate objective is to develop a human infectivity model using a nasally administered influenza virus vaccine with which to examine the effects of concurrent exposures. The effects of the pollutant on nasal virus levels, on the duration of virus shedding on local interferon production, and on influenza virus specific secretory antibody levels will be studied using this human infectivity model.

DETERMINE IMPACT OF PROXIMAL LIVING TO LEAD, COPPER AND ZINC SMELTERS ON TRACE METAL BURDEN

R. Handy, Research Triangle Inst., *P.O. Box 12194, Research Triangle Park, North Carolina* 27709 (68-02-2442)

Trace metal absorption study of 1680 persons of different ages will be conducted in 2 zinc - 2 copper smelter communities. Demographic data/blood/hair/urine specimens/housedust/tap water/air samples will be obtained. Samples will be analyzed for Pb/Zn/Cu/As/Cd/Mn. Conclusion of chemical analyses at end of February. Review of draft final report. Final report on first 3 sites and pretest site expected at end of March.

A STUDY OF CANCER AND THE PUBLIC DRINKING WATER SUPPLIES IN MISSOURI

C.J. Marienfeld, University of Missouri, Columbia Campus, School of Medicine, Dept. of Environmental Health, *M228 Medical Sciences, Columbia, Missouri* 65201 (R805297-03)

OBJECTIVE: To determine if drinking water contaminants are contributing causes for observed variations in cancer rates among counties and water service areas in Missouri.

APPROACH: Cancer mortality rates are computed for, and compared among, geographic areas defined by occurrence of drinking water contaminants, water treatment practices, etc.

PROGRESS: Some interesting relationships have been observed in the cancer death rates in Missouri and water supply characteristics. Supplies have been classified as to impact of coal mining and burning. Results from the epidemiological studies seem promising enough to continue. If more consistent relations are developed some more chemistry and bioassay would seem warranted.

ANALYSIS OF EPIDEMIOLOGICAL STUDIES OF COMMUNITY HEALTH AND AIR POLLUTION EXPOSURE

C.M. Shy, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514 (68-02-2763)

During the period 1970 to 1975 EPA collected some 82 data sets relating health to air pollution. The overall project was given the acronym CHESS. During the next several years only 19 of these data sets were published. A congressional investigation demanded that the remaining data sets be reviewed - and those of higher quality be reported in the peer reviewed literature. Because there was insufficient inhouse manpower to complete this task, a contract was let with UNC to analyze and publish some of these data sets. 36 data sets were selected and furnished to UNC. The contract calls for 12 to 21 reports covering these 36 data sets. The contractor has had 3 reports reviewed by an external committee. We have received no reports for our review.

SIMS THREE-YEAR STUDY ON STATISTICS AND ENVIRONMENTAL FACTORS IN HEALTH

D. Thomsen, S.I.A.M., *33 S. 17th St., 1405 Architects Bldg., Philadelphia, Pennsylvania* 19103 (R804932)
SIAM Institute for Mathematics and Society (SIMS) is directing the statistical research personnel at Columbia and Stanford Universities. The investigators are developing more sophisticated techniques for the analysis of environmental and health data. Whittemore has developed a model for the combined effects of cigarette smoke and asbestos exposure on cellular atypia in sputum. A statistical program is being written for the application of the model. This research will elucidate the role of both factors in the development of lung cancer. She has also addressed the problem of estimating human cancer risk at low doses of environmental carcinogens, in particular the sensitivity of risk estimates to implicit assumptions in the mathematical model, preparing survey article on air pollution and health for the Annual Review of Public Health. Steele completed SIMS working paper number 14 entitled 'Red Flags on the Houston Study.' This was a review requested by EPA of the 'Study of Health-Related Responses to Air Pollution of Persons with Chronic Obstructive Pulmonary Disease in Houston, Texas.' Switzer has been investigating the problem of areal mapping using remotely sensed observations. The usual discriminant analysis techniques do not take into account spatial continuity. Foo has studied the hourly and daily variations of ozone concentrations. Her statistical model was used to estimate the frequency distribution of the duration of elevated concentrations - an important question for exposure modeling in epidemiological studies and in the setting of standards. One should be able to see how this duration distribution is affected by changes in mean levels. Galfond has examined the problem of estimating waiting times between pollution episodes. With commonly used extreme value models such waiting time estimates can be very unstable statistically as well as noticeably biased unless care is taken in the estimation of the model parameters.

3.1297,

ASSESSMENT OF HEALTH IMPACT OF FILTERING ASBESTIFORM FIBERS IN DULUTH

E. Sigurdsen, State Dept. of Health, *717 Delaware St. S.E., Minneapolis, Minnesota* 55440 (R805428-02)
OBJECTIVE: Determine the relationship - or document the lack of one - between asbestiform fibers in the water supply and cancer.
APPROACH: Gather incidence data on cancer in the population of Duluth, Minnesota and compare with cancer rates in the Minneapolis-St. Paul component of the National Cancer Survey to test whether exposure to asbestiform fibers in the drinking water may contribute to the cancer rate.
PROGRESS: Data collection in progress, analysis of 1969-1974 gastrointestinal cancer incidence data did not show any definite relationship between ingesting asbestiform fibers and cancer. The long latency period between exposure and cancer for asbestos necessitates ongoing surveillance.

SELECTION/CHARACTERIZATION OF AREAS FOR PARTICULATE EPIDEMIOLOGIC STUDIES DETERMINED IN INHALABLE PARTICULATE PROBLEM DEFINITION STUDY

Unknown, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *Research Triangle Park, North Carolina* 27711
Selection of communities to be studied is an important part of epidemiologic research. Proper evaluation of socioeconomic, demographic, and exposure parameters help identify communities that satisfy the needs of study and thus help insure that studies provide valuable data for the agency. This task is a major in-house effort to select appropriate communities for future studies of particulates. Communities will be identified by levels of particulates and other pollutants and characterized with respect to demographic, socioeconomic, industry type, climatic and other selected parameters. This will allow the selection of communities to be monitored in the coordinated task. Based upon the data acquired above, communities will be selected that best fulfill the research needs of the studies determined by the inhalable particulates problem definition study.

INORGANIC ANALYSES TO SUPPORT EPIDEMIOLOGIC STUDIES

K. Kelty, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Field Studies Div., Water Analysis Group, *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVE/APPROACH: To provide inorganic analyses for epidemiological studies. Samples of drinking water are being analyzed for a variety of parameters, including pH, conductivity, hardness, alkalinity, fluoride, nitrates, Na, Mg, Li, Be, Si, Pb, Cd, Cu, Zn, and Fe.

OUTPUTS: Analysis of 1,000 Boston drinking water samples (4,092 elemental determinations). Analysis of 630 Boston tissue samples (2,520 elemental determinations).

SIGNIFICANT RESULTS: A new method for the determination of Pb and Cd has been evaluated and successfully applied. It consists of a modification of Middleton's digestion procedure (Analyst: 79, p. 138-147) and an adaptation of Henn's atomic absorption method (ASTM STP, pp 54-64).

PROGRESS: Approximately 700 analyses of drinking water samples for 3 studies (2 cardiovascular and 1 asbestos pipe) have been completed. The analyses for the second phase of the Boston Body Burden Study are being initiated. 2200 elemental determinations of phase 2 Boston drinking water samples completed.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab. $40,000

3.1311,

DETECTION OF UNCULTURABLE ENTERIC VIRUSES

E.W. Akin, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVE: To detect in human specimens the viral etiological agents (and specific antibody) of waterborne gastroenteritis and hepatitis A that cannot be cultivated, and thereby identified, in vitro.

APPROACH: Establish serological tests such as RIA, ELISA and IEM and then apply these tests to specimen collected in HERL-supported waterborne outbreak investigations.

PROGRESS: IEM of rotavirus in infant diarrheal stools has been accomplished. Small viral particles have been observed in stools of humans associated with waterborne enteritis outbreak. In vitro cultivation has been unsuccessful.

3.1312,

EFFECTS OF ELEVATED LEVELS OF DRINKING WATER SODIUM ON BLOOD PRESSURES OF SCHOOL CHILDREN IN TEXAS AND OKLAHOMA

C. Sonich, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Epidemiology Branch, *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVE: To replicate, under identical circumstances, a recent study reported by the University of Massachusetts, Amherst, Massachusetts. In that study, the distribution of blood pressures of school children in a high sodium (108 mg/L) community was significantly skewed upward when compared to the children of a low sodium (8 mg/L) community. The current study will compare two communities with high and low sodium levels, 286 mg/L and 22 mg/L respectively. This will be done to replicate the earlier findings and to ascertain a dose/response relationship.

APPROACH: The blood pressures of 7th grade students will be taken by standardized individuals in the schools of both communities. The same standardized individuals will be used in both communities. All students will complete a questionnaire. For a subset of approximately 100 children in each community a 24-hour diet diary will be completed and home water samples and first morning urine samples will be collected and analyzed for sodium and potassium content. They will also be sent to Purdue University for 40 elemental analysis.

PROGRESS: No significant results to report, however, the data must be 'cleaned'. Frequency distributions were the body of the preliminary report which show some differences in blood pressures between communities. Differences were also found within the high sodium community. This is due to varying water sources within the community.

3.1317,

DISEASE TRANSMISSION ASSOCIATED WITH LAND APPLICATION OF WASTEWATER

H.I. Shuval, Hebrew University of Jerusalem, Hadassah Medical School, *P.O. Box 1172, Jerusalem 91000, Israel* (R806416-01)

OBJECTIVE: 1) To determine and measure if there is a degree of added risk of communicable disease incidence associated with wastewater land application and irrigation in agricultural communities (kibbutzim). 2) To determine the relationship between routes of transmission and disease incidence in the study population.

APPROACH: A prospective epidemiological study will be carried out in 30 kibbutzim in Israel which practice wastewater irrigation and in control groups not irrigating with wastewater. Health records of the various population groups will be studied and epidemiologic follow-ups of highly susceptible groups will be made (visiting volunteers, etc). Serologic and other lab tests will be used to compare infection rates of exposed and control groups. Air monitoring studies for aerosolized bacteria and viruses will be carried out.

A STUDY OF THE DISTRIBUTION AND HEALTH EFFECTS OF GIARDIA LAMBLIA IN DOMESTIC WATER SUPPLY

F. Frost, State Health Div., *Olympia, Washington* 98504 (R805809)

OBJECTIVE: Determine the occurrence of giardiasis in human populations and the occurrence of Giardia in watershed animal populations in Washington State; determine the extent to which water supplies may act as the vehicle for transmission of giardiasis.

APPROACH: Contacts will be made with all physicians and diagnostic laboratories in the state to improve case reporting; 5-year retrospective data will be analyzed to determine seasonality; a case-control study will be completed to determine association of cases with drinking water; specimens of animal intestinal contents will be solicited from trappers; filtered water samples will be examined for the organism.

PROGRESS: A widespread distribution of human cases of giardiasis has been revealed in Washington State. Infected beaver and muskrat were found in 20 counties. Giardiasis occurs in many small outbreaks, among travelers, persons with backcountry exposures, children and in isolated cases with no obvious source.

INVESTIGATION OF WATERBORNE DISEASE OUTBREAKS

R.E. Stetler, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVE: Identify causative agent in outbreaks and determine how contaminant entered system so corrective measures can be implemented.

APPROACH: Microbiological agents are isolated by large volume sampling techniques for laboratory identification using culture and nonculture methodology. In-depth investigation of the water system identifies route-of-entry and provides basis for corrective measures.

PROGRESS: Investigate 4-6 outbreaks annually. Continue to improve techniques and methodology so agent isolation is improved from current 50% detection rate. Publicize deficiencies in water systems that permit outbreaks to occur so similar conditions in other systems can be corrected.

SCREEN SERA FROM AEROSOL EPIDEMIOLOGICAL STUDIES FOR ANTIBODY TO LEGIONNAIRES' DISEASE BACTERIUM

T.H. Ericksen, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Field Studies Div., Epidemiology Branch, *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVE: To determine if sewage and/or its treatment is a possible route of exposure for persons to Legionnaires' Disease Bacteria (Legionella pneumophila).

APPROACH: Sera already obtained from sewer workers and persons living in the neighborhood of sewage plants, will be tested for antibodies to LDB using the IFA method developed by Center for Disease Control, Atlanta, Georgia. These results will be compared to those obtained from the sera of control groups. The results obtained from this study could determine the role of sewage as a possible source of LDB in the environment, thereby contributing to its spread and exposure to susceptible populations.

PROGRESS: Training of personnel in the methodology to be used is complete. Arrangement for transfer of the necessary equipment under revocable license is in progress. Some of the reagents necessary for testing have been obtained from Center for Disease Control. Several hundred serum samples have been obtained as part of other studies of persons associated with sewage, sewage plants or residing in the vicinity of such facilities. The fluorescent microscope has been repaired and alloy the necessary reagents for testing by indirect fluorescent antibody methods have been obtained.

HEALTH EFFECTS STUDY FOR THE LUBBOCK LAND TREATMENT PROJECT

D.E. Johnson, Southwest Research Inst., *8500 Culebra Rd., P.O. Drawer 28510, San Antonio, Texas* 78228 (R807501-01)

OBJECTIVE: Determine if there is an increased risk of infectious disease in a human population as a result of spray irrigation of municipal wastewater.

APPROACH: People living on or near the wastewater application site will be monitored through a health watch for disease incidence and serologic evidence of infection. Environmental samples of wastewater, ground water, and air will be monitored for pathogens. Exposure indices will be developed by correlating environmental results with meteorologic data. Disease incidence and serology results will be correlated with exposure indices.

AN EPIDEMIOLOGICAL STUDY OF PRESQUE ISLAND STATE PARK BEACHES ON LAKE ERIE, ERIE, PENNSYLVANIA

S.J. Zagorski, Gannon College, Undergraduate School, Dept. of Biology, *109 W. 6th, Erie, Pennsylvania* 16501 (R806791 01)

OBJECTIVE: The objective of this proposal is to correlate the incidence of illness among bathers with the quality of water as indicated by results of bacteriological assays obtained from fresh recreational water sites on Lake Erie, Erie, Pennsylvania. The sites selected are expected to differ substantially in water quality, one known to be impacted by contamination and the other relatively clean. Computer assisted analysis of the data will employ a SAS program already developed. Objectives of original study have been expanded to include second summer of bacteriological and epidemiological investigations.

APPROACH: Conduct bacteriological and epidemiological surveys at the beaches and by telephone follow-ups. Microbial assays include those for Escherichia coli, Clostridium perfringens, and enterococci. Results of these studies should amplify the development of fresh recreational water quality criteria.

PROGRESS: Bacteriological surveys pinpoint the source of contamination impacting one of the test beach areas and show no impact on the other site selected. All assay procedures, survey forms, and statistical analyses procedures to be employed have been used successfully in other research programs.

3.1324,

DEVELOPMENT OF PEST MANAGEMENT FOR SOIL INSECTS ON CORN

M.L. Fairchild, University of Missouri, Columbia Campus, School of Agriculture, Dept. of Entomology, *130 Jesse Hall, Columbia, Missouri* 65201 (R8054290-03)

OBJECTIVE: The project goals seek to improve corn soil insect population assessment and damage prediction capability and develop insect pest management strategies. The specific objectives seek to improve the ability to detect potentially damaging Arthropods (cut worms, corn rootworms and wire worms); refine corn soil insect population assessment techniques; refine soil arthropod damage thresholds; identify, evaluate and optimize control alternatives; utilize modeling techniques to assess corn insect population dynamics, host-crop interactions, and insect-host dynamics resulting in a management decision model; and to develop a pest management strategy for implementation.

APPROACH: The work is done by a six-institution consortium: the University of Missouri (head institution), Purdue University, Illinois Natural History Survey, Iowa State University, University of Nebraska, the Ohio Agricultural Research and Development

Center. The work includes field and laboratory study. Several technical models - larval dynamics, parasite efficiency, larval migrations and a soil insectacide model - are under study. From these an overall farm level decision model is being developed that will assist the corn growers with on-farm control decisions.

PROGRESS: Quarterly Reports - First Annual Report 1978 - Second Annual Report 1979 Corn Ecosystem Publications (EPA/IPM Library). Detection of populations has improved but still lacks precision. New trapping methods using pheromones have been highly evaluated. Corn root and plant models have been nearly completed. Economic and management models are being structured and adjusted.

VIRUS SHEDDING AND IMMUNITY DURING ISOLATION IN THE ANTARCTIC

H.G. Muchmore, Oklahoma Medical Research Foundation, *825 N.E. 13th St., Oklahoma City, Oklahoma* 73104 (DPP80-19528)

The research objectives of this project are to carry out virus-specific immunoassays on frozen specimens, to obtain information confirming and extending the remarkable and unexpected frequency of parainfluenzavirus shedding which was encountered during the winter of 1978. These frozen specimens (serum, nasopharyngeal secretions, etc.) have been obtained serially from men spending the winter in isolation at the South Pole.

Radioimmunoassay (RIA) and enzyme-linked immunosorbent assay (ELISA) will be utilized for virus specific serum assays, and for measurement of virus-specific secretory Immunoglobulin A (sIgA) in nasopharyngeal secretions. The sensitive RIA and ELISA methods will be further refined and extended to achieve direct detection of the virus antigen(s) in the still-frozen original W/O 78 nasopharyngeal secretions.

If successful, these immunoassays should provide direct confirmatory evidence for persistent parainfluenzavirus shedding we observed during the winter of 1978 at the South Pole and for the winter of 1976 and earlier years for which we so far have only serological evidence for persistent virus shedding.

Confirmation of respiratory virus persistence and shedding into the nasopharynx will further the understanding of the epidemiology of these infections and provide clues which may prove helpful in unraveling the problems of immune response patterns in these ubiquitous infections. The results will guide the way for the planning of subsequent isolation studies at the South Pole.

A STUDY OF RESPIRATORY VIRUS TRANSMISSION AMONG THE PERSONNEL AT MCMURDO STATION, ANTARCTICA, DURING THE 'WINDFLY' ISOLATION PERIOD

E.C. Dick, University of Wisconsin, Madison Campus, Medical School, Dept. of Preventive Medicine, *450 N. Randall Ave., Madison, Wisconsin* 53706 (DPP80-15486)

The University of Wisconsin proposes to continue studies on the transmission, etiology and control of upper respiratory viral infections among members of a small and isolated population of persons winteringover in Antarctica, following exposure to viruses carried by new arrivals at the end of the winter. An attempt will be made to repeat the work of 1979 when virus transmission was apparently interrupted through the ritualized use of virucidal handkerchiefs. Studies will also be made of the effectiveness of less ritualized use of the handkerchiefs and to extend the experiments to other groups as appropriate. Another goal of this program is to increase knowledge of the etiology of respiratory illness outbreaks in Antarctica using electron microscopy, tissue culture, and other techniques until the agents causing the diseases are identified. These studies build on the rich results of prior years and will include extensive analysis of the new and earlier data.

SUPPORTED BY U.S. National Science Foundation, Directorate for Astronomical Atmospheric Earth & Ocean Scis., Div. of Polar Programs $95,185

A STUDY OF RESPIRATORY VIRUS TRANSMISSION AMONG PERSONNEL IN ISOLATION IN ANTARCTICA

E.C. Dick, University of Wisconsin, Madison Campus, Medical School, Dept. of Preventive Medicine, *450 N. Randall Ave., Madison, Wisconsin* 53706 (DPP76-83918)

The University of Wisconsin proposes an investigation of person-to-person transmission of common cold viruses in an isolated population of 200 at McMurdo Station, Antarctica. This population is unique in that it consists of normal American citizens (primarily United States Naval personnel) with their normal complement of colds who will suddenly be completely isolated for about 5 weeks. It should be possible during this period to follow the movement of common cold viruses through this population without 'outside viruses' entering the chain of infection. Careful study of the characteristics of each person's illness and the inter-personnel methods by which person-to-person transmission can be interrupted. This approach seems promising, as prior studies in open populations and in human volunteers suggest that colds may be more difficult to transmit than previously supposed.

Analysis of data detained during the 77/78 field season will be carried out at the University of Wisconsin, Madison.

This research represents a continuation of that currently supported by DPP-7683918.

SOCIOECONOMIC DETERMINANTS OF CHANGES IN MORTALITY RATES

A. Palloni, University of Wisconsin, Madison Campus, School of Letters & Science, Dept. of Sociology, *500 Lincoln Dr., Madison, Wisconsin* 53706 (SES80-21410)

Latin America has experienced long term increases in life expectancy and decreases in mortality rates that exceed the change rates for the transition period in Europe. Yet, recent signs indicate a slowdown in change rates for Latin America that may still keep the continent below the pace-setting standards of Europe. This research seeks to provide a more detailed specification of the Latin American change rates and an explanation for them over the last seventy years. Among factors affecting mortality decline, the study considers the impact of endogenous developments (i.e., rising standard of living) and exogenous developments (introduction of new and low-cost medical technology). The study will trace the separate and joint effects of these developments on overall mortality and changing variation in the cause and rates of mortality by levels of socioeconomic status. The research employs available documentary data from death registrations, population censuses, and other records. This research should help extend basic knowledge of empirical regularities in trends and causes of human deaths, leading to the day when general theories of mortality change can be more confidently advanced.

THE SIMULATION OF INFLUENZA DIFFUSION

G.F. Pyle, University of North Carolina, Charlotte Campus, Graduate School, Dept. of Geography, *Hwy. 49 N., Charlotte, North Carolina* 28205 (SES80-06637)

From past experience it is known that the spread of a new strain of influenza virus throughout the country into a nonimmune population can have serious consequences. While a number of hypotheses exist that help to explain the spread, little is known of the actual process by which an influenza virus diffuses throughout geographic space. In part, this is because the origin locations of viruses tend to differ with different strains. In part also, it is because geographic changes occur from one time to another in the factors involved in the diffusion process: population size, travel patterns and transport infrastructure linkages, for example. The purpose of this research is to modify and apply current methodologies used to describe and explain the temporal-spatial diffusion of other phenomena to simulate the spread of influenza. Such methods take into account various propositions hypothesized to be associated with the spread of diseases and include simulation techniques employed in hierarchical, linear and radial diffusion processes.

The research will perform several simulation experiments using different hypothesized variables to replicate the 1946 and 1957 influenza diffusion patterns. The relationships between each simulated pattern will be statistically tested against the actual pattern for specific penetration periods of the influenza season. Using the results of this research, the 1968 pattern will be simulated and the relationship to the actual pattern tested statistically.

The knowledge obtained from the research can be used to simulate the spread of new influenza viruses for which barriers can be created to hinder its progress. The knowledge would be applicable to other disease agents known to diffuse in a geographic fashion.

VALUING THE HEALTH EFFECTS OF AIR POLLUTION

M.L. Cropper, University of Southern California, School of Letters Arts & Sciences, Dept. of Economics, *3551 University Ave., Los Angeles, California* 90007 (DAR79-24990)

The research will measure the dollar amount an indivdual would pay for a decrease in air pollution by focusing on willingness to pay and on acute illness. The research differs in two ways from the conventional method of valuing air quality. The traditional approach calculates the effect of changes in pollution of life expectancy and then values changes in life expectancy using foregone earnings. This traditional method is likely to understate willingness to pay by ignoring the value of leisure time and by ignoring the health effects of pollution while the individual is alive.

To remedy these shortcomings this research will develop a model of acute illness which follows the human capital approach to health economics. The essence of the model is that the individual makes choices regarding his health, taking into account the health effects of pollution. The model will be used to define willingness to pay for a change in air quality and an equation suitable for estimating willingness to pay will be derived from the model. The model will thus provide a technique for valuing the acute health effects of air pollution.

STATISTICS AND ENVIRONMENTAL FACTORS IN HEALTH

D.L. Thomsen, S.I.A.M., *33 S. 17th St., 1405 Architects Bldg., Philadelphia, Pennsylvania* 19103 (MCS79-07549)

Dr. Thomsen will coordinate an effort in which research statisticians at Stanford University (specifical-

ly, Professors Switzer, Mittal, and Faith, in the first year) will work on a variety of theoretical problems in statistics necessary to the development of new methodology for evaluating air pollution data. Some specific statistical areas involved are as follows: 1) Design of experiments for assessing the relationship between station network data and the distribution of exposures in a population. (Switzer) 2. Problems of selection of variables for relating meteorology to air pollution in a statistical framework. (Switzer) 3. Statistical validation of air pollution simulation models and the analysis of forecasting errors. (Switzer and Faith) 4) Problems of network design for measurement of a random field applied to air pollution. (Faith) 5) Analysis of the distribution of maximum concentrations from averaged air pollution data. (Mittal) 6) Sampling theory for estimation of maximum concentrations with sampling rates depending on preceding data. (Mittal)

PROBLEMS IN FUNCTIONAL DIFFERENTIAL EQUATIONS WITH APPLICATIONS IN BIOLOGY

K.L. Cooke, Claremont Colleges, Pomona College, Undergraduate School, Dept. of Mathematics, *Claremont, California* 91711 (MCS79-03497 A01)

This is a continuation of work supported by MCS-79-03497.

Investigations will be carried out which will extend and continue work on differential, difference and functional differential equations. By-products of these efforts are applications to ecology, epidemiology and the physical sciences.

Of particular interest are classes of functional differential equations which arise in the modeling of the transmission of disease. Emphasis will be placed on understanding the interactions between periodicities induced by seasonal variations of the coefficients and those due to nonlinearities in the equations.

Work will also be done on classes of equations arising from ecological and epidemic models which take into account age dependence and spatial dispersal, on stability of linear delay equations and on the analysis of models of vertically transmitted diseases.

MEDICAL AND PHYSICAL STUDIES OF MERCURY IN THE ENVIRONMENT AT ALMADEN, C.R., SPAIN

R. Wilson, University of Rochester, School of Medicine & Dentistry, Dept. of Radiation Biology & Biophysics, *601 Elmwood Ave., P.O. Box 607, Rochester, New York* 14642 (INT78-19907)

Mercury has been mined from the region of Almaden, Spain for two thousand years. Even today, the mines produce over one quarter of the world's mercury supply. The miners, residents and general environment of Almaden have thus been exposed to mercury at unusual levels for an extensive period of time.

This multi-faceted project involvng U.S. and Spanish scientists is directed at gaining a better understanding of the impact of mercury in the environment in and around the mining area. Studies are being carried out on the levels of airborne mercury in the town and the mines and on the occupational exposure of underground and refinery workers. Also, methods are being developed for assessing body burdens of mercury and for quantifying various diagnostic, therapeutic and prophylactic measures such as chelating agents.

PROJECTION MODELS FOR HEALTH EFFECTS ASSESSMENT IN POPULATIONS EXPOSED TO RADIOACTIVE AND NON-RADIOACTIVE POLLUTANTS

D. Grahn, Argonne National Lab., *9700 S. Cass Ave., Argonne, Illinois* 60439

OBJECTIVE: The objective is to assess the potential health effects and life-shortening resulting from exposure to effluents from the uranium and coal fuel cycles. This requires development of a demographically correct projection model to predict mortality for any population of specified age, race, and sex composition.

SCOPE: The project consists of five tasks: 1. Basic Demographic Model. This stage provides the demographic framework into which the other stages fit. The basic demographic projection model will predict deaths by age, sex, and cause as well as predicting the population structure by age and sex. 2. Simple Dose-Response Functions. Dose-response coefficients for several types of cancer as a function of exposure in rem without consideration of dose-rate will be obtained from BEIR-III. Total mortality and specific causes of death for exposure to air pollutants will be made using the cigarette model. 3. Morbidity Projections. Models will be developed to derive person-years lived while in states of ill health from the causes of death treated by the mortality analyses. 4. Advanced Dose-Response Functions. More sophisticated and realistic dose-response models will be developed to incorporate dose-rate effects and nonlinear responses into estimates of both the total effect and the duration of latency for all pollutant types. 5. Interactions among Short- and Long-Term Effects. Short-term radiation effects for acute exposures are well known and will be incorporated into the models. The effects of short-term fluctuations in air poliutants are superimposed on health impairments that may have accrued from previous exposure.

SCOPE OF WORK FOR FY 1980: Task 1. The adequacy of the Poisson probability density function for numbers of births will be investigated. Monte Carlo techniques will be used to develop error bounds for all dose-response functions. Task 3. Estimates of the incidence of diseases will be made based on probability distributions for the time between diagnosis and death. Age-specific morbidity projections will be derived. Task 4. Nonlinear and rate-dependent radiation dose-response models will be completed and indices for different radiation types will be attempted. The model for chemical carcinogenesis will be initiated.

DETERMINATION OF FEASIBILITY OF CONDUCTING EPIDEMIOLOGIC STUDIES OF HUMAN HEALTH EFFECTS OF LOW LEVEL IONIZING RADIATION

N. Dreyer, Health Systems Inc., *100 Main St., Reading, Massachusetts* 01867 (160175 TICNO)

The major objective is determination of the feasibility of conducting epidemiologic studies of human health effect of low-level ionizing radiation. This is a project in two phases. Phase I presents suitable epidemiologic approaches to be used in determining health effects from exposure to low-level ionizing radiation. In addition, Phase I includes the selection of suitable exposed population which may be used for human epidemiologic studies. Phase II examines the quality of actual field data on the population selected in Phase I. In addition, those populations, if any, most suitable for further study will be selected. Such things as cost, time needed for followup studies, and how data bases need to be improved are also part of Phase II.

THORIUM-230 IN URANIUM MILL WORKERS

D. Fisher, U.S. Dept. of Energy, Battelle Pacific Northwest Lab., *P.O. Box 999, Richland, Washington* 99352 (160167 TICNO)

The contractor will collect and interpret data concerning the degree of accumulation of 238-U and 230-Th in the tissues of uranium mill workers. The specific purpose is to determine whether 230-Th may be present in higher concentrations than 238-U in the tissues of long-term workers and to compare these and other measurements to the predictions of ICRP's models of human physiology. The contractor will identify a population of approximately 30 workers who have at least 5 years work experience in crushing operations at approximately 5 uranium mills. The contractor will measure the 238-U and 230-Th in the urine and feces of each worker on the first day following a work interruption of at least days. Retired employees will be included in the study if possible. Exposure histories will be recorded.

FOREIGN BODY TUMORIGENESIS AMONG WAR VETERANS

R.J. Struba, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514

OBJECTIVE: Considerable laboratory evidence and scattered clinical reports have implicated chronic exposures to foreign bodies (FB) in the induction of soft tissue tumors - principally the sarcomas. Latencies are thought to be long here (more than 30 years) and the chemistry of the FB does not appear to be important - glass beads, metal and plastic chips all lead to increase in incidence of these tumors.

APPROACH: This hypothesis of FB tumorigenesis is being evaluated in a population of war veterans. Using a case-control design, U.S. Veterans Administration sarcoma patients and matched non-sarcoma controls are being compared on past exposure to any FB and, particularly, to combat-related metal fragments in wounds or implants. Matching factors and other potential confounders are being examined in the analysis. Data are being gathered by review of medical records and by personal interviews with study subjects.

CANCER IN LA. - A CASE-CONTROL STUDY OF LUNG, STOMACH AND PANCREAS CANCER

P. Correa, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *510 E. Stoner Ave., Shreveport, Louisiana* 71130 (256-52-7076)

The aim of this investigation is to identify factors associated with the high cancer rates that Louisiana has been shown to have. The study is designed to determine whether the excess in lung cancer mortality is due to smoking alone or to smoking in combination with other evironmental factors. An assessment will be made of the independent actions of various factors as well as their interactive and synergistic effects. Diet and occupational history will be especially important in assessing risk of cancers of the stomach and pancreas.

The study is a case-control design with noncancer controls matched to cancer cases on the basis of race, sex, hospital and age within five years. Additionally, certain medical conditions that have been strongly associated with smoking have been excluded as controls for lung cancer cases. The effect of this selection of controls should be to sharpen the contrast between the cases and the controls with respect to cigarette smoking and bring the other factors which are operating in lung cancer more sharply into focus.

Data will be gathered in face-to-face interviews by highly trained interviewers in the hospital or in the patient's home if a hospital interview is not possible. The interview contains residential, occupational, smoking and drinking water histories as well as information on diet, exposure to irritants and other questions.

Patients with cancer will be found in the files of the Pathology Department and Tumor Registry. Control patients will be found in admission records.

AN EPIDEMIOLOGICAL STUDY OF DIABETIC RETINOPATHY

J.J. Chosy, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *2500 Overlook Ter., Madison, Wisconsin* 53705 (271-26-1051)

OBJECTIVE: To study the prevalence and severity of diabetic retinopathy in a group of 2400 diabetic patients in their home communities.

RESEARCH PLAN: First year we will ascertain diabetics living in 11 county area. In the second and third year we will examine patients. In the fourth year we will analyze the data.

METHODOLOGY: We will objectively record retinopathy by use of stereoscopic fundus photographs combined with a standarized protocol for grading retinopathy. The association between the prevalence severity of retinopathy and risk factors such as smoking and high blood pressure level will be examined utilizing analysis of variance and other statistical techniques for multiple variables.

RESULTS: During the first year of the study over 450 physicans participated (representing 98.6%) of all primary care physicians treating diabetic patients in an eleven county area. The names of 9,700 participants were ascertained and information regarding prevalence rates, age of the onset duration types of treatment and indices of control are being determined. Currently participants are being examined in a mobile van. The examination consists of refraction and best corrected visual acuity, intraocular pressure check, fundus photography, ophthalmoscopy, blood pressure determination, height, weight and glycosolated hemoglobin determination.

ASSESSMENT OF CADMIUM EXPOSURE AND TOXICITY RISK IN AN AMERICAN VEGETARIAN POPULATION

M.G. Crane, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Endocrine Metabolism Section, *11201 Benton St., Loma Linda, California* 92357 (549-32-8348)

A 72-hour food and stool sample, a 24-hour urine sample, and a fasting blood sample have been collected in 50 lacto-ovo-vegetarians and 50 matching meat eaters from enrollees in the Adventist Health Study (AHS) in Southern California (Santa Barbara to San Diego counties). An epidemiologist supervised the collection. These samples are stored frozen and are in process of analysis. From an initial pool of several hundred subjects listed in the AHS study as pure vegetarians, we found 32 who were such. Nineteen have been recruited for the study and either have or shall collect the food, stool and urine samples as above. We were disappointed that so many who considered themselves to be pure vegetarians were in actuality lacto-ovo-vegetarians. It appears at this point impossible to accumulate 50 total vegetarians, unless we look outside Southern California. Technical aspects of tooling up the system for tissue digestion have been essentially completed. We find that a microwave oven arrangement is capable of wet digestion of the samples at a much faster rate (ten fold) in comparison with the conventional wet and sand heating baths. We find that location of the samples in the microwave, adjustment of power level, and adequate hydrogen peroxide are all important factors in proper sample digestion. Hair sample collection has proved impractical in live subjects in spite of incentives of a free hair styling, but we do not consider this an important loss in view of known technical inaccuracy of hair analysis. Preliminary results indicate that urinary beta-2-microglobulin concentrations are greater in lacto-ovo-vegetarians than their matched non-vegetarian controls (N equals 23 first 30 pairs).

A BASIC RESEARCH PROGRAM TO STUDY THE ETIOLOGY OF ALCOHOLISM

M.A. Schuckit, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Alcohol Treatment Program, *3350 La Jolla Village Blvd., San Diego, California* 92161 (388-42-0398)

This project tests the possibility that biological mediators of a genetic propensity in alcoholism could include personality factors and/or unique aspects of the metabolism of ethanol and/or unique attributes of the acute reaction to moderate alcohol doses. The study is carried out by comparing these factors in pairs of men aged 21-25 matched on demography, height/weight ratio and drinking history, half of whom have an alcoholic first degree family member (the family history positive of FHP group) and half of whom have no such family history (the family history negative of FHN group). Individuals are tested under baseline conditions and after the administration of 0.75 ml of absolute ethanol per kilogram which is administered as a 20% solution and consumed over 5 minutes. To date over 2,000 young men have been screened from whom 118 individuals were tested in the laboratory. Differences between FHP and FHN groups have included the finding that FHP men demonstrate higher levels of acetaldehyde after an ethanol load. The FHP group has also consistently demonstrated less intense subjective, physiological, and psychomotor changes after drinking. The final year of study will involve a continuation of intensive testing of these parameters.

VIRAL HEPATITIS AND DENTAL PRACTICE

E.R. Schiff, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Hepatology Section, *1201 Northwest 16th St., Miami, Florida* 33125 (271-32-7788)

Dental personnel and dental patients are at risk to develop viral hepatitis. The identification and subsequent refinement of serological parameters for type B virus allows for more definitive epidemiological studies of viral B hepatitis. The purpose of this study on hepatitis and dentistry is to examine the development of hepatitis among VA dental personnel, and to determine the magnitude of potentially infectious dental personnel who chronically carry type B virus. The study deals with the prospective passive screening of dental personnel for type B infection, either a chronic state or acute viral hepatitis. If this initial study generates a significant number of chronic carriers with serological evidence of infectivity, a protocol will be submitted for second study designed to characterize the risk of transmission of type hepatitis from such carriers to susceptible patients. Preliminary results show that the dental group at the highest risk are the oral surgeons, but dental hygenists are also at an equal risk to develop hepatitis as general dentists are. The attack rate of hepatitis during the period of the study is quite low, therefore it appears that most of the hepatitis has been acquired during the period of training.

PROSPECTIVE STUDY OF THE PREVALENCE OF LEGIONNAIRES' DISEASE IN VETERANS WITH PNEUMONIA

P. Edelstein, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Research Service, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (545-66-4479)

More progress has been made with the clinical microbiology and serology of L. pneumophila. Sixty-one strains of L. pneumophila have been isolated from clinical specimens, a third of which were sputum specimens. The development and use of a semiselective medium has facilitated the recovery of L. pneumophila from contaminated clinical specimens. Almost half of all clinical isolates have been recovered using only a newly developed semiselective medium. The average time for isolation and identification of the organism has been shortened from five to three days. An additional new serogroup of L. pneumophila has been isolated and characterized in this laboratory. More isolates have been obtained from blood as well. Further definition of the reliability of these diagnostic tests has been shown to cross-react with the direct FA reagents. Fourteen manuscripts have been published, or are in press as a result of such work. Several more have been submitted for publication.

3.1349,

ORIGIN AND SIGNIFICANCE OF MYCOBACTERIUM XENOPI IN CLINICAL SPECIMENS

J.E. Hawkins, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Special Reference Lab for TB & Other Mycobacterial Diseases, *W. Spring St., West Haven, Connecticut* 06516 (253-44-7141)

Various aspects of this study have been reported over the past several years at national and international meetings and in scientific literature. A complete report of the clinical & roentgenographic features of Mycobacterium xenopi disease in 19 patients at the West Haven VAMC will be published in the Jan. 1981, issue of the Am. Rev. Respir. Dis. (A. Costrini, D. Mahler, W. Gross, J. Hawkins, R. Yesner, N. D'Esopo). The findings were summarized as follows: 'this report strongly suggests that (1) nosocomial pulmonary disease resulted from the presence of M. xenopi in the hospital water system from an unknown source; (2) antecedent lung disease and prolonged environmental patterns were observed: nodular or mass shadows, cavities, and multiple nodular densities; and (4) disease due to M. xenopi was generally successfully treated with standard antituberculosis drugs.

Studies conducted in our laboratory provided information on the chemical and thermal stability of the specific strain of xenopi contaminating the hospital water. Through the cooperation of the Engineering Service, a regular schedule of cleaning and heating water tanks and the maintenance of generators at a slightly higher temperature have resulted in a reduction in viable organisms in the system which appear to be continuing to decline. Although M. xenopi has not as yet been completely eliminated from the water lines, problems of colonization of patients and repeated isolations from clinical material have significantly diminished.

Since the basic objectives of this investigation have been accomplished, it is being terminated as an official, but non-funded, research project. The laboratory will, however, continue to monitor isolates of xenopi from patients as well as to test the hospital water on a regular basis.

ALCOHOL DRINKING PATTERNS IN VETERANS

A.S. Wilson, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *5000 W. National Ave., Wood, Wisconsin* 53193 (073-28-1036)

OBJECTIVE: This project is designed to evaluate the patterns of alcohol consumption present in several veteran populations.

PLAN: A questionnaire is used to provide a self report of monthly alcohol consumption. This report produces a quantity-frequency index for comparison purposes.

METHOD: The groups of veterans to be compared are: diagnosed alcoholics under treatment in the VA Medical Center; veterans diagnosed as having cirrohsis of the liver without a primary or secondary

diagnosis of the liver and a random sample of other veteran with neither set of diagnosis.

CLINICAL RELATIONSHIP: A strong similarity existing in the alcoholic and liver disease groups in the absence of similarity with the random group will suggest recommendations for treatment.

THIRTY-YEAR CLINICAL FOLLOW-UP OF SELECTED DEMYELINATING DISEASES

J.F. Kurtzke, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neurology Service, *50 Irving St. N.W., Washington, District of Columbia* 20422 (133-16-2851)

This study was designed to assess the late course of 762 elisted men diagnosed as MS and 183 diagnosed as optic neuritis (ON) in US Army hospitals during World War II.

Prior assessment of the ON group to the mid-1960s indicated only 12% of them had developed MS, with a projected lifetime expectation of 15% plus or minus 5%.

The ON cases have been reviewed, to include the bases for the original diagnosis. On preliminary assessment, about 10 cases have been discarded from the 183 as erroneous diagnoses, and only some 24 cases of MS have been ascertained from World War II to July 1977. This provides a provisional rate of about 14% for progression to MS over the ensuing 30 plus years since ON onset. Further work is in process to provide precise life table analyses, to search for prognostic features of progression to MS, and to assess recurrent ON.

3.1352,
HUMAN IMMUNE RESPONSE DURING BIO-ISOLATION

H.G. Muchmore, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Tuberculosis Section, *921 N.E. 13th St., Oklahoma City, Oklahoma* 73104 (446-05-4218)

This project involves the study of human immune changes which occur during isolation at the South Pole. Our research objectives are to carry out virus-specific immunoassays on frozen specimens, to obtain information confirming and extending the unexpected frequency of parainfluenzavirus shedding which was encountered during the winter of 1978. These frozen specimens (serum, nasopharyngeal secretions, etc.) have been obtained serially from men spending the winter in isolation at the South Pole. Radioimmunoassay (RIA) and enzyme-linked immunosorbent assay (ELISA) are being utilized for virus specific serum assays, and for measurement of virus-specific secretory Immunoglobulin A (sIgA) in nasopharyngeal secretions. The RIA and ELISA methods will be further refined and extended to achieve direct detection of the virus antigen(s) in the still-frozen original W/O 78 nasopharyngeal secretions.

If successful, these immunoassays should provide direct confirmatory evidence for persistent parainfluenzavirus shedding we observed during the winter of 1978 at the South Pole and for the winter of 1976 and earlier years for which we so far have only serological evidence for persistent virus shedding. Confirmation of respiratory virus persistence and shedding into the nasopharynx will further the understanding of the epidemiolcgy of these infections and provide clues which may prove helpful in unraveling the problems of immune response patterns in these ubiquitous infections.

3.1353,
HEARING PROFILES OF A DOMICILED VETERAN POPULATION

D.K. Smith, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Martinsburg, West Virginia* 25401 (308-54-1067)

Evaluation of the data from audiologic test batteries, administered consecutively to 358 Domiciliary patient-members at the time of their annual physical examination, revealed a steady decline in pure tone thresholds, speech reception thresholds, and speech discrimination ability with an increase in age. This finding is consistent with other published studies which have been concerned with the relationship between reduced auditory acuity and advancing age. Comparison of mean pure tone thresholds for the total population studied (N equals 358, x age 60 years) with those reported in a Public Health Survey (1962) suggests increased severity of hearing loss in a domiciled veteran population. The significance of noise exposure in a veteran population is discussed. Of the 358 patient-members tested, 7% (or 25) had speech reception thresholds of 30 decibels or poorer in the better ear; 12% (or 45) had discrimination ability of 80% or poorer in the better ear.

The final report on this project was not presented last year because it was hoped to finalize the findings in the form of a paper at a scientific meeting. However, this was not accomplished. Therefore, the above results which were also reported in April 1979, constitute the final report on this project.

PROSPECTIVE GENETIC STUDIES OF COLON AND LUNG CANCER

M.J. Swartz, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *4101 Woolworth Ave., Omaha, Nebraska* 68105 (507-30-0806)

Purpose of this investigation was to study all new patients with carcinoma of the lung at the Omaha Veterans Administration Hospital in order to identify genetic factors by an interview technique. The study was part of a larger review by the Department of Medicine of Creighton University which was funded by the Council of Therapeutic Research. In May 1980 the project at Omaha Veterans Administration Hospital was admitted to cover other tumors including cancer of the oral cavity, pancreas and bladder. Under the antecedent protocol approximately twenty patients of carcinoma of the lung were studied. With the appending protocol approximately fifteen additional patients were interviewed by December 1980. At the present time under the appending protocol no results have yet been obtained. It is anticipated that the interview study will be continued for this coming year.

TRI-COUNTY STUDY OF CANCER OF THE MOUTH, ESOPHAGUS, LARYNX, STOMACH, COLON, RECTUM, LUNG AND BLADDER

S. Graham, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *3495 Bailey Ave., Buffalo, New York* 14215 (069-18-3175)

PROJECT OBJECTIVES: (1) To study the epidemiology of cancer of the gastrointestinal tract, lung and bladder, and (2) to study the possible relationship between dietary factors and cancer at the aforementioned sites.

PLAN AND METHODS: We are attempting to interview all patients in Erie, Niagara and Monroe Counties who develop histologically confirmed neoplasms of the gastrointestinal tract, lung and bladder. Fifteen patients at the Veterans Administration Medical Center have been entered in the study since the last report.

The major emphasis in the interview is on dietary habits. Questions are asked about time and frequency of eating meals, types and amounts of food eaten, and methods of food storage and preparation. In addition, questions are asked about alcohol consumption and use of tobacco. Certain data such as age, occupation and marital status are gathered.

In addition to interviewing cases, we are also interviewing neighborhood controls matched on age (plus or minus 5 yrs.) and sex.

FINDINGS, RESULTS: We have not undertaken any definitive analyses of our data since the numbers at various sites are still too small. We have, however, completed a methodological study based on this series which examines degree of agreement between case-spouse and control-spouse pairs with regard to food frequency. We presented our findings on this at the meeting of the Society for Epidemiologic Research on June 14, 1979.

NATIONAL COOPERATIVE EVALUATION OF HYDROCORTISONE

D.S. Schreiber, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *1400 Vet. of Foreign Wars Pkwy, West Roxbury, Massachusetts* 02132 (081-36-1213)

The present study, using a placebo and being double-blind in its evaluation of patients, it is intended to answer the following questions: (1) does hydrocortisone in large doses improve survival in acute hepatic encephalopathy? (2) does hydrocortisone given for encephalopathy decrease survival in the immediately post-encephalopathy period because of steroid-induced complications?, (3) does hydrocortisone given for encephalopathy influence the incidence of subsequent chronic hepatitis among survivors?

This study is a national multicenter effort because of the scarcity of suitable subjects. Consequently, since fulminant hepatic failure is a very rare disease, we have not entered any patients into this study in the past 12 months.

STUDY ON THE PSYCHODYNAMICS OF CANCER II

R.S. Picard, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *510 E. Stoner Ave., Shreveport, Louisiana* 71130 (723-18-8761)

OBJECTIVE: (1) To determine childhood psychosocial factors that contrbute to the susceptibility of certain adults for giving up hope when deprived of what is their single specific reason for life. The sequential hopelessness has been cited as a precipitating factor in malignancies' onsets. (2) To discriminate this parameter from tobacco in each respective role in the genesis of lung cancer.

PLAN: A structured questionnaire was submitted by an oral interviewer to 658 patients on appropriate wards at VAMC Shreveport. These were separated into lung cancer (LC), alcoholic (Alc), continuing smokers (CS), ex-smokers (XS), never smoking (NS) groups.

METHOD: 81 items were submitted to t or X2 analyses. The 20 significant items were then analyzed via the SPSS multiple regression subprogram. Randomized cross validation studies (RCVS) were performed on second half-samples, after determining an optimum function on the first half.

RESULTS: Correcting for age, RCVS distinguished the LC from the Alc at less than .01 level (X2 equals 7.611: df equals 1) with sensitivity of 67%, specificity of 65%. Continuing LC smokers could not be distinguished from CS, nor CS from NS or XS from NS, though CS discriminated from XS at less than .05 level.

Factors separating LC from Alc included less rebellion, less overnight stays away from parents, less relatives near, more mothers working, greater age difference Proband and next older male, yet less age difference between him and next older sibling and more parents smoking.

Cardiac diagnoses are now being coded for similar analyses. Yearly review of new cancers among non-cancers is planned to determine if RCVS has prospective worth.

3.1358,
LIFE EVENTS AND PSYCHIATRIC DISTURBANCE

I. Grant, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *3350 La Jolla Village Blvd., San Diego, California* 92161 (163-42-8598)

Life Events and Psychiatric Disturbance was a controlled prospective study of changes in these two phenomena among groups of psychiatric outpatients and normals. Results indicated that undesirable events were substantially related to somatic and dysphoric symptoms. Desirable events were inversely related. Fourier analyses showed little coherency between events and symptoms. Markovian analyses determined that event or symptom characteristics of subjects were best predicted by their state in a measurement period immediately prior to the one being considered. More historical data added little to predictive power. These analyses and other studies strongly suggest that the Schedule of Recent Events as currently used is unreliable, with little predictive validity in longitudinal studies of life change and illness.

The current project, Life Events, Coping Skills and Health Status in the Elderly, is derived from the above investigation. This prospective study will describe the relationship between life event and health changes among 200 elderly persons in the community. The temporal relationship between life events and health will be studied through consideration of the moderating variables of coping skills, personality, social support, age and social position. Given that the elderly population is increasing in our county and given that these elderly are more vulnerable to health changes, especially chronic disease, it becomes important to determine whether there any 'controllable' and/or predictable aspects to illness onset and recrudescence.

FAMILIAL INCIDENCE AND MULTIPLE MANIFESTATIONS OF MEDULLARY CARCINOMA OF THE THYROID

G.A. Williams, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Nuclear Medicine & Endocrinology Section, *820 S. Damen Ave., Chicago, Illinois* 60612 (578-38-5346)

The purpose of this study continues to be to evaluate all family members of patients with diagnosed medullary carcinoma of the thyroid. This evaluation includes a) clinical evaluation, b) serum calcitonin by radioimmunoassay before and after calcium infusion, c) serum parathyroid hormone by radioimmunoassay, d) urinary catecholamine determination. In any patients in whom abnormalities are found, appropriate therapy will be carried out. In those subjects in whom the studies are normal, repeat studies will be done at 6 to 12 month intervals. In this way, this study should a) lead to early diagnosis and treatment of patients with medullary carcinoma of the thyroid before clinical manifestations are apparent, and b) yield additional information about the incidence, inheritance and natural history of this disease.

During the past year, 8 additional new patients suspected of medullary carcinoma of the thyroid have been evaluated, but the studies were normal in all of these patients. The one patient who was identified as a strong suspect for medullary carcinoma of the thyroid last year is in Europe and is not yet available for reevaluation. This patient will be more thoroughly investigated and family members will be evaluated as soon as she returns to this area.

This study continues.

CELL-MEDIATED IMMUNITY IN LIVER DISEASES

F. Paronetto, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Laboratory Service, *130 W. Kingsbridge Rd., Bronx, New York* 10468 (084-32-8328)

Studies have continued on the liver specificity of the cell membrane lipoprotein 'LSP' (liver specific protein) and the importance of antibodies to LSP in chronic liver disease. Contrary to other reports, our study gave evidence that LSP is not organ-specific and that it shares antigenic determinants with its kidney equivalent KSP, as well as with another soluble liver antigen, LP-2, and with saline-insoluble liver cell membrane proteins. We are now attempting to isolate pure liver-specific antigens and to produce monospecific antibodies against these components. We are planning to achieve this goal by producing monoclonal antibodies by the cell fusion technique and by isolation of pure antigens by affinity chromatography.

The leukocyte adherence technique (LAT) has been utilized to assess cell-mediated immunity (CMI) to HBcAg and HBsAg in patients with chronic (CH) and acute viral (AVH) hepatitis. All patients with AVH type B and 91.6% of patients with HBV-related CH displayed reactivity to both HBcAg and HBsAg, whereas healthy controls and patients with liver disease not related to HBV failed to show reactivity to these antigens. Four of 6 laboratory workers who had been exposed to HBsAg and had no signs of hepatitis and 2 of 17 patients with CH unrelated to HBV who received multiple tranfusions exhibited reactivity to HBsAg but not to HBcAg. These results suggest that according to the LAT, reactivity to HBcAg is present in patients with active HBV replication, whereas, reactivity to HBsAg alone indicates previous exposure to HBV.

MORBIDITY AND EFFICACY OF INFLUENZA VIRUS VACCINE IN HIGH RISK INDIVIDUALS

J.P. Lucas, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Martinsburg, West Virginia* 25401 (235-70-0067)

Three hundred four volunteers were enrolled from amongst the patient-members of the Domiciliary and the patients of the Medical Service at the VA Medical Center in Martinsburg. Ninety-four have since been eliminated from the study, leaving a total study population of two hundred ten. One hundred sixty-five high risk patients accepted vaccination with commercially obtained, inactivated influenza vaccine (1975-76 bivalent vaccine) and constituted the final experimntal Group I. Group II is comprised of thirty high risk subjects who refused vaccination. Groups I and II were shown to be of comparable composition by age and indices of disease. There was no significant difference between the vaccinated and unvaccinated groups in the frequency of acute respiratory illness as determined by the 'new respiratory illness' reports completed by the physician assistants. There are no scientific conclusions available at this time because the serologic data have not been released by the Bureau of Biologics, Food and Drug Administration.

THE CONTROL OF MAMMALIAN PROTEIN SYNTHESIS AT A MOLECULAR LEVEL

M. Civen, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *5901 E. 7th St., Long Beach, California* 90822 (012-22-8942)

Plasma high density lipoprotein (HDL) has been shown to be the main source of cholesterol used by the rat adrenal cortical cell for the synthesis of steroid hormones. HDL is bound at a high affinity receptor site on the adrenal cortical cell membrane. HDL binding and uptake is stimulated by ACTH. HDL is transported from the cell surface to the lysosomes where the protein is degraded and cholesterol released. Cholesterol is then transported to the mitochondria where it is converted by the cytochrome P-450 cholesterol side chain cleavage system to pregnenolone, the first steroid. Pregnenolone by multiple enzyme systems is converted to corticosteroids. It was observed by us that HDL, when incubated alone with adrenal cortical cells, induces a two-fold increase in corticosterone production. In the presence of both 3'5'-cyclic adenosine monophosphate (cAMP) and HDL, corticosterone production was stimulated 100 fold. Both in the presence and absence of cAMP, large amounts of cholesterol derived from HDL are taken up by the adrenal cell.

Apparently in the cell which is not stimulated by cAMP, cholesterol though taken up by the cell, is either not transported into the mitochondria, or if it is, is not bound to the cholesterol side chain cleavage system, and therefore not converted to steroids. It will be our next task to study the translocation of cholesterol from the cell membrane through the lysosomes to various other intracellular fractions. The intracellular fractions of the adrenal cells will be homogenized and separated centrifugally using the appropriate marker enzymes to determine the purity of these fractions. They will then be analysed for free and esterified cholesterol. This work will take about two years.

NOTES ON THE ETIOLOGY OF MULTIPLE SCLEROSIS

J.F. Kurtzke, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neurology Service, *50 Irving St. N.W., Washington, District of Columbia* 20422 (133-16-2851)

Other aspects of MS epidemiology are covered in active projects #08, 11, 12. Period cumulative risk estimates for MS by age at entry and sex have been calculated. For an unaffected population, all ages, only some 1/8 of expected cases will begin within five years and only about 1/2 the total within 20 years of follow-up. In the US there is no relation of the distribution of MS with that of canine distemper or dog-bites. In Iceland, there as at least one epidemic of MS: from 1945-54 the average annual incidence rate of 3.2 per 100,000 was twice that of preceding or following periods.

FUNCTION-STRUCTURE CORRELATION IN PULMONARY DISEASE

P.C. Pratt, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Laboratory Service, *508 Fulton St., Durham, North Carolina* 27705 (128-26-7115)

PROGRESS REPORT: Three major projects are in progress at this time.

Experimental exposures to asbestos dust in rats. This is a joint project with the NIEHS. Exposures and animal sacrificings are carried out at the Research Triangle. Tests are designed to reveal the relative importance of short vs long fibers of asbestosis. This is a disease of increasing importance because of the wide use of asbestos in many industries and especially in the U.S. Navy. Better understanding of mechanisms involved is urgently needed. Experimental findings indicate that long asbestos fibers are more toxic than short fibers or particles.

Morphology and epidemiology of pulmonary lesions in human Byssinosis. This study involves special preparations of lungs obtained at autopsy in patients dying in this hospital. The inflated lungs are subjected to morphometric determination of extent of various lesions (emphysema, bronchitis) thought to be associated with cotton dust exposure. Results suggest that bronchitis is related to this occupation but emphysema is not. The study is continuing, with efforts to obtain greater details as to work history and symptoms among the cotton workers, most of whom are in this hospital because of other intercurrent diseases.

Studies of Cystic Fibrosis. This is a joint study with clinical workers at Duke. Autopsies are done at Duke and specially prepared lungs are studied in the laboratory using techniques similar to those in the Byssinosis project.

BIBLIOGRAPHIC REFERENCES: Pratt, P.C., Vollmer, R.T., and Miller, J.A. Epidemiology of pulmonary lesions in non-textile and cotton-textile workers: A retrospective autopsy analysis. Arch. Environ. Health., 35:133-138, 1980.

AN EPIDEMIOLOGICAL SURVEY OF SYMPTOMS IN DEPRESSION

W.W. Zung, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *508 Fulton St., Durham, North Carolina* 27705 (101-22-4743)

PURPOSE: Depression as a psychiatric disorder consists of signs and symptoms, which if based on organic changes in the central nervous system should manifest similar psychopathology regardless of country or culture. In addition, depression has been frequently observed to occur concomitantly with anxiety. Often, it is difficult to be able to distinguish on the initial examination as to whether the patient is depressed only, anxious only, or has both anxiety

and depression. In order to increase the accuracy of the epidemiological survey of depression, we have surveyed the symptoms of anxiety as well, using the previously published, validated and standardized self-rating scale for anxiety.

METHODS & RESULTS: The self-rating anxiety scale was translated into various foreign languages by collaborating investigators, and administered along with the depression scale. Each collaborator worked within their own practice setting, and provided data for the data analysis performed. Data gathered in Nigeria, Korea, and Taiwan was compared to data obtained in the USA. As much as possible, patient populations were matched, and patients were divided into diagnostic categories.

Results of the data analyses demonstrated that normal subjects in the USA, Nigeria, Korea and Taiwan did not differ on their anxiety ratings, and were not significantly different from each other. Patients with diagnosis of anxiety states all rated significantly higher than normals, and were not different from each other.

PRESENTATION: How normal is anxiety? Am. Psychopath. Assoc., Washington, DC, March 6, 80.

AN EPIDEMIOLOGIC STUDY OF AMYOTROPHIC LATERAL SCLEROSIS AND OTHER MOTOR NEURON DISEASES

J.F. Kurtzke, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neurology Service, *50 Irving St. N.W., Washington, District of Columbia* 20422 (133-16-2851)

For 504 male veterans of World War II who died of ALS between 1963 and 1967, comparisons with 504 matched controls from the military showed a significant excess of trauma and operations.

Preservice injuries number 38 in the ALS and 16 in the controls. Injuries of upper and/or lower extremities were 32 ALS vs 12 controls. Preservice operations were 29 ALS vs 14 controls.

Injuries during service also predominated in the ALS: fractures were 40 vs 18, lacerations 42 vs 26, contusions 20 vs 11 as the major groups. Sprains and strains were equivalent (22 vs 24). Extremity fractures were particularly discrepant at 27 ALS vs 12 controls; skull fractures were 9 vs 3. The causes of injury (combat, vehicular, falls, sports) were all equally in excess among the ALS.

One hypothesis is that direct muscle trauma long before clinical onset is a predisposing factor in ALS; this may also explain the known male predilection for the disease.

A LONGITUDINAL AND CROSS-SECTIONAL STUDY OF ORAL HEALTH IN HEALTHY VETERANS

H.H. Chauncey, U.S. Veterans Admin., Dept. of Medicine & Surgery, Outpatient Clinic, *17 Court St., Boston, Massachusetts* 02108 (031-12-1877)

PROJECT OBJECTIVES: The specific aim of this investigation is to determine the incidence, distribution, changes, and interrelationships of oral variables used to indicate oral health. Information is obtained during periodic examination, performed at three-year intervals, of more that 1,200 DLS participants.

PLAN: This oro-facial study includes six series of examinations or procedures: 1) interim health history; 2) oro-facial examinations; 3) tests of masticatory function and survey of dietary habits; 4) biochemical analyses of stimulated whole and parotid saliva; 5) intra-oral and cephalometric radiographs, standardized photographs and study models of the teeth; 6) oral cytological examination.

METHOD: These comprehensive oral examinations permit a detailed description and analysis of the effect of age on oral tissues and functions and elucidate the natural history of oral diseases.

CLINICAL RELATIONSHIP: The DLS determined the prevalence of oral leukoplakic lesions in 'nonsmokers' and persons who smoked either cigarettes, cigars, pipes or cigars plus a pipe. The data indicated that the prevalence of oral leukoplakia was associated with smoking and differed according to the type of product used. Individuals smoking a 'pipe' or 'cigars plus a pipe' exhibited the highest overall prevalence rate, especially for the palate.

Changes in masticatory ability with age were primarily due to the loss of natural dentition with subsequent replacement by a removable prosthesis. Approximately 1,200 men were classified by denture status. A plot of masticatory performance vs. mean perceived chewing ease, for thirteen food items, separated out the dentition groups by degree of impairment. A clustering of the dentition groups occurred. The robustness of the clusters suggested that characteristic food selection patterns can be formulated according to degree of impairment.

HLA B27 RELATED ARTHROPATHIES - GENETICS VERSUS ENVIRONMENT

A. Calin, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Rheumatology Section, *3801 Junipero Serra Blvd., Palo Alto, California* 94304 (500-56-3324)

We have now identified 150 patients with ankylosing spondylitis and their first degree relatives. Likewise, 130 patients with Reiter's Syndrome have been evaluated. These individuals have formed part of a presentation and publication (CALIN A, FOX, Gerber: The natural history of Reiter's Syndrome. Arthritis Rheum 21:548-549, 1978)

We have identified patients with a reactive arthropathy following salmonella and shigella epidemics. We have determined that Shigella sonnei does not cause Reiter's disease in contrast to flexneri 1 and 2a, both arthritogenic agents. (CALIN A, Simon, Kaslow, et al: Seroepidemiology of shigella and Reiter's Syndrome. Ann Rheum Dis, in press, 1979)

We are beginning to identify immune complexes and other evidence of immunological activity in our patient population.

Specific family units consisting of probands with psoriatic arthropathy and identical twin member have been studies. (Gottlieb, Calin: Discordance for psoriatic Arthropathy in phenotyypically identical (monzygotic) twins. Arthritis Rheum, in press, 1979)

EPIDEMIOLOGICAL & BIOCHEMICAL STUDIES ON MYCOBACTERIA & THEIR VIRUSES

J.H. Bates, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *300 E. Roosevelt Rd., Little Rock, Arkansas* 72206 (429-54-0024)

We have made considerable progress in our efforts to develop a phage typing scheme for M. avium-intracellulare. Over 20 phage strains that infect these organisms have been identified. Sixty strains of M. avium-intracellulare were typed using 12 phages, and 28 strains were found to be sensitive to at least one of the phages. Most importantly, pairs of strains of the same serotype generally had the same phage senstivity. Our current work is directed towards isolating additional phages, determining the precise conditions which yield the highest reproducibility of typing, and determining the affect of colony variability on phage type. In several months we will begin to screen fresh clinical isolates of M. avium-intracellulare to determine the general applicability of our typing phages.

We have extended our studies of plasmids (extrachromosomal genetic elements) of M. avium-intracellulare. Having previously demonstrated that strain LR25 carries three plasmids, we observed that this strain has a restriction-modification (RM) system. This was demonstrated by its resistance to phage JF2 grown in M. smegmatis but sensitivity to JF2 grown in LR25. We have succeeded in eliminating the plasmids from LR25. This 'cured' strain no longer exhibits RM and is sensitive to a number of phages. We are currently attempting to determine which of the three plasmids codes for RM and what other functions are plasmid-coded.

Five other strains that carry plasmids were found to be resistant to all of our phages, and the results indicate that this resistance is not due to restriction of phage DNA. Additional studies on the relationship between plasmids and phage sensitivity are underway.

GENETIC HETEROGENEITY OF HYPERURICEMIA

E.M. Short, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *3801 Junipero Serra Blvd., Palo Alto, California* 94304 (041-34-7400)

This project is designed to assess the contribution of single major genes to the common adult male phenotype hyperuricemia using the newer techniques of quantitative genetics. Previously identified major gene mutations in pathways of urate homeostasis can be detected in less than 5% of patients with common adult hyperuricemia. A multifactorial model for inheritance of this phenotype has been postulated. We are determining serum urate and urate excretion under strictly controlled conditions designed to minimize environmental effects on urate homeostasis in entire pedigrees chosen through an index case male with longstanding hyperuricemia (serum urate greater than 8.0mg%). Studies on 94 such pedigrees are nearing completion. When all living first degree relatives have been studied, segregation analysis will be done using computer techniques developed for study of quantitative phenotypes (MAXLIK-Morton and GENSEG-Elston). A quantitative urate phenotype is being developed using a single bivariant analysis of serum and urine data since we postulate a two locus model of inheritance of the phenotype serum urate. Computer simulations for such data analysis are being run. Preliminary analyses of each variable individually have been undertaken. Analyses on pooled data from incomplete families show within sibship variance ratios and present-offspring correlations suggestive of the contribution of major genes of large effect to the inheritance of serum urate in older sibships. Analyses of completed nuclear families by the methods of Carmelli and Karlin using Major Gene Index and Offspring Between Parent analysis as a measure of major gene segregation, show asymmetry of inheritance with a greater maternal contribution for serum urate and results compatible with major autosomal gene segregation for fractional urate excretion (MGI 1.059-1.141). These results in urine data analysis have necessitated further study of urate excretion in a control population. In May 1980, we began a control study in a stratified random population sample of 2500 persons in collaboration with the Stanford Lipid Research Center.

AUTOMATIC CARDIOVASCULAR DATA PROCESSING

H.V. Pipberger, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *50 Irving St. N.W., Washington, District of Columbia* 20422 (579-52-0549)

Trend analysis of electrocardiograms from a prospective study on 1,600 normal middle-aged and elderly men from Albany, N.Y., was continued. Since the study was started in the early fifties, the age of the subjects in the study has now advanced to the point that the number of yearly cardiac events (infarcts and/or cardiac death) is increasing rapidly. ECG records from patients with events were compared with those without events. Highly significant differences were found (P less than 0.001) particularly in the ST segment of the vertical lead y. The ECG parameters which were identified are now being tested as risk indicators for future events.

The ECG record collection from children has been terminated. The number of tracings from normal children is 4,055 and from abnormals with cardiac catheterization 2,268. The records are being divided into subgroups according to diagnosis and are being prepared for publication.

Three different ECG lead systems, the standard 12-lead ECG, Frank's orthogonal ECG and body surface maps consisting of 126 leads were correlated in 139 patients with left ventricular mass determined by biplane ventriculograms. Correlation coefficents were 0.61, 0.78 and 0.89 respectively. Even with total body surface maps, the error of estimate was too large for practical application.

Compression of digital ECG records is desirable for economic use of storage space and for transmission of multiple leads by telephone. Various compression methods were tested. Interpolation was found most efficient and a compression ratio of 9:1 could be achieved.

The high frequency content of the electrocardiogram has been considered by many as contributing diagnostic information which cannot be obtained from low frequency components. This hypothesis was tested in 542 records from cases with autopsy confir-

mation of the diagnosis. The gain in information through high frequency components was found negligible.

CLINICAL AND INFECTIVITY CORRELATES OF E ANTIGEN

R.P. Perrillo, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *915 N. Grand Blvd., St. Louis, Missouri* 63106 (116-34-6562)

This project had as its major aim to determine if the presence of hepatitis B e antigen and elevated DNA polymerase activity in the serum of chronic hepatitis B surface antigen carriers indicate increased contagiousness in a household setting. The household contacts of 74 carriers were prospectively evaluated for serologic evidence of hepatitis B infection. Both household contacts of HBe antigen-positive and anti-HBe-positive carriers demonstrated serologic evidence of infection, but infection was significantly more frequent among spouses and sexual partners of carriers who had either HBeAg or elevated DNA polymerase activity (P less than 0.001). Thus, the data indicate that particular subpopulation of spouses and sexual partners of hepatitis B carriers are at significantly greater risk for acquiring infection. This data was published in a manuscript form in Gastroenterology vol. 76: 1319, 1979.

3.1374,
HEPATITIS B VIRUS INFECTION IN AN ONCOLOGY UNIT

L.B. Seeff, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *50 Irving St. N.W., Washington, District of Columbia* 20422 (338-42-5556)

The intent of this study is to define the incidence and prevalence of Hepatitis B Virus markers in the staff assigned to the Oncology ward. Other scientific studies have already identified Oncology ward staff and patients as being in a high risk area. We would like to show evidence of type B hepatitis and to take steps toward limiting the transmission of the virus. All staff have been assured that their right of confidentiality will be protected. This is necessary to protect individuals against unreasonable actions such as endangering their jobs and/or preventing upward mobility. There are 86 persons entered into the study which is proceeding without complications. All testing has been completed except HBeAg and anti-HBe which is commercially unavailable. We expect to be able to perform these tests shortly using test materials designated for research purposes only. There are no preliminary conclusions to be drawn because the nature and design of the study must be continued until completion before an analysis of the data can be made.

INCIDENCE OF AVASCULAR NECROSIS IN PATIENTS ADMITTED TO AN ACUTE ALCOHOLIC TREATMENT CENTER

R.D. Lynch, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Wrightsboro Rd., Augusta, Georgia* 30904 (238-74-1188)

OBJECTIVES: To determine the incidence of avascular necrosis in patients admitted to an acute alcoholic treatment unit.

RESEARCH PLAN: Patients were asked to fill out a brief questionnaire dealing with possible hip pathology and were given a brief hip examination upon admission.

METHODOLOGY: A routine frog leg lateral to the pelvis with all admissions was instituted along with the questionnaire.

RESULTS: The initial 200 patients involved in this study showed a surprisingly low incidence of avascular necrosis. One man with avascular necrosis had already had total hip surgery on the opposite side so he was known to have had avascular necrosis. The second man with some limitation upon physical examination had questionable avascular necrosis.

CLINICAL RELATIONSHIP: This study may show whether alcoholism in some way predisposes patients to this particular disease.

INVESTIGATIONS ON LEGIONNAIRES' DISEASE

S.M. Finegold, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Infectious Disease Section, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (550-14-6341)

The Wadsworth outbreak of Legionnaires' disease is now the longest on record (over two years and still active). We have documented the disease in 104 patients; this makes ours the largest hospital-associated outbreak.

Preliminary analysis of autopsy material from prior to opening of the new hospital indicates that the disease is related to opening of the new facility. Legionella pneumophila was recovered from our cooling tower water, but hyperchlorination (which eliminated the organism) had not modified the outbreak. Additional efforts are underway to attempt to end the outbreak; these involve ground cover, air control, and air filtration.

We have reported (Lancet) the first in vitro recovery of L. pneumophila from blood culture and we have two additional blood culture recoveries now. A new serogroup (IV) of the organism was recovered from a patient at Wadsworth; it is designated serogroup Los Angeles. Our clinical experience with Legionnaires' disease has been documented in an article in Lancet (renal transplant cases), one in Annals of Internal Medicine (our first 24 cases), and one accepted by Medicine (65 cases and a literature review). The Faine silver impregnation stain was found to stain Legionella well in tissues. A semiselective medium has been developed to facilitate recovery of the organism from specimens containing other organisms. We have the greatest experience of any group with documentation of the disease by direct fluorescent antibody staining and cultivation of the organism.

RELATIONSHIPS BETWEEN LEAD IN HOME DRINKING WATER, CARDIOVASCULAR RISK FACTORS AND OTHER HEALTH INDICES

A.J. Garvey, U.S. Veterans Admin., Dept. of Medicine & Surgery, Outpatient Clinic, *17 Court St., Boston, Massachusetts* 02108 (033-32-1192)

PROJECT OBJECTIVES: To examine relationships between lead and other trace metals found in home drinking water and indices of health, with particular emphasis on cardiovascular health.

PLAN: The study is being performed in collaboration with the National Heart, Lung and Blood Institute (NHLBI) and the Environmental Protection Agency (EPA). Samples of home drinking water and nail clippings were collected from 325 Normative Aging Study (NAS) subjects in 1976-1977 and analyzed for metallic contents by the EPA in Cincinnati. A follow-up collection of water and nail clippings was completed on the same subjects in August 1979. The 1979 data have been analyzed by the EPA. Health data are regularly collected as part of subjects' NAS physical examinations.

METHOD: A data set linking trace metal data from the 1976-1977 water samples to NAS health data is currently being analyzed by both NAS and NHLBI. Analyses relating hypertension to trace metal exposure controlling for age, education, town of residence and other confounder variables have been performed.

FINDINGS: Analyses to date have not found significant relationships of lead, zinc, and copper to hypertension. Elevated levels of cadmium, however, have been found to be associated with lower diastolic blood pressures.

3.1378,
TO DETERMINE THE INCIDENCE OF SECOND PRIMARY MALIGNANCIES FROM THE PATIENTS' CHARTS AT WEST HAVEN VA HOSPITAL

R.J. Papac, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Hematology & Oncology Service, *W. Spring St., West Haven, Connecticut* 06516 (537-26-0360)

The purpose of this study was to examine retrospectively, from medical record room indexing, the occurrence of second primary malignancies in this hospital.

It is postulated that second malignancies are increasing, as a consequence of more affective tumor therapy with longer survival and also a consequence of treatment modalities which are carcinogenic.

For purposes of this assessment, data on patients with differing histology as well as site were to be considered criteria for second primaries. This would exclude patients with multiple skin malignancies, and patients with multiple head and neck tumors.

EPIDEMIOLOGY OF LEGIONNAIRE'S DISEASE IN A VETERAN POPULATION EXPOSED TO A MAJOR CONSTRUCTION PROJECT

D.P. Nicholson, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *300 E. Roosevelt Rd., Little Rock, Arkansas* 72206 (453-76-0494)

Serology testing commenced in earnest toward the end of 1979. The laboratory technician started in October, and with training time and awaiting the arrival from CDC of polyvalent antigen for L. pneumophilia serogroups 1 through 4, some delay occurred. The polyvalent antigen is to be replaced shortly by an improved preparation.

Long-term patients in the North Little Rock Division, VAMC, tested in January 1979. Fifty-three sera have been re-run against polyvalent antigen and a further seven sera were positive at greater than or equal to 1:128. This infers a prevalence of 23% rather than 10%. The new positives included some to serogroups 2-4.

A sample of hospital personnel, construction site workers, and nursing students from out of town, revealed positive serology (greater than 1:128) in 4.5% of personnel, and in less than 1% of the other two groups. Ambulant day care ex-patients from Building 105 revealed six positive in 23 volunteers (26%). Retesting sera of American Legion volunteers from the area confirmed the initial positive rate of 2%.

Since October 1979, four new clinical cases have been proven, by serology or direct staining of sputum or tissue. Three arose at the North Little Rock Division and one at the Little Rock Division. Two had recent therapy for malignancy. Two died of the disease, and one succumbed several weeks later.

A number of 'suspect' cases have been observed, but not proven.

Linda Dickinson, Ph.D. (Division of Biometry) has used the initial prevalence survey as a pilot model to determine the information needed in the long-term study. A structured analysis specification has been drawn up to define interphases between various aspects, laboratory data, patient profiles, and statistical analysis. The data collection system is based on a daily gains and losses log, with quality control checks. Computerization is underway to include files of data base, and ability to process, retrieve, and edit information.

INVESTIGATION OF A CHANGING CLINICAL PRESENTATION OF PNEUMOCOCCAL PNEUMONIA

S.I. Ort, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *W. Spring St., West Haven, Connecticut* 06516 (314-36-1889)

A twenty month retrospective and prospective study of one hundred and ninety-four subjects admitted to or residing in a community hospital and a Veterans Administration Hospital, in whom pneumococci were isolated from sputum and/or blood cultures, was analyzed. Population characteristics, presence of underlying pathologic conditions, presenting symptoms, conditions predisposing to aspiration, and admission radiologic findings were evaluated. Eighty percent of cases had one or more associated underlying disease processes over half were associated with radiologic features of bronchopneumonia in contrast to lobar infiltration (25 percent). The sputum Gram stain suggested pneumococci as the causative pneumonia agent in a high percentage of cases regardless of type of radiologic presentation and/or the presence of bacteremia. Pneumococcal polysaccharide capsular antigen typing of 37 patient isolates identified 20 different types, 62 percent of which are included in the Pneumovax vaccine. Pneumococcal pneumonia has a wide range of clinical presentations from those subjects admitted with clinical symptoms but no radiologic evidence of disease to fatal cases with bacteremia. Awareness of the range of clinical presentations of pneumococcal pneumonia in this compromised population may affect better earlier diagnosis and prompt appropriate therapy.

ANTECEDENTS OF ALCOHOLISM - SELF-REPORTED CHILDHOOD MINIMAL BRAIN DYSFUNCTION WITH ADULT DRINKING BEHAVIOR AND PSYCHOSOCIAL ADAPTATION

C.G. Lauterbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Psychology Service, *1481 W. 10th St., Indianapolis, Indiana* 46202 (485-07-4840)

This investigation focusing upon whether a homogeneous group of alcoholics can be differentiated on the basis of childhood signs of minimal brain dysfunction (MBD) was begun October, 1979. It requires extensive interviewing, testing, ratings upon 80 Alcohol Treatment Unit patients and 3 control groups. The latter consists of a normal group of General Medical and Surgery inpatients, a Drug Treatment Unit (DTU) group and a Mental Health Clinic (MHC) group. Basic data have been collected, processed and preliminary computer statistical analysis performed for the ATU group. Data thus far indicates many relationships between childhood MBD signs and adult adaptation of the ATU subjects (severity of alcoholism, and adult personality and life experiences, as well). Also, measures of current brain functioning show relationships to severity of alcoholism among ATU subjects. However, these varied relationships appear to be more complex than those thus far reported in the research literature. Most data have been obtained from control groups, with some interviewing still needed from 5 MHC patients. Collateral data obtained by phone from relatives of patients are still being collected for experimental and control subjects. It is anticipated that data collection will be completed in the current quarter. Substantial progress toward completing necessary group comparisons and all appropriate multi-variate analysis is expected in FY 1980. Several papers for submission for publication are being planned for preparation throughout FY 1981.

EPIDEMIOLOGY, GENETICS, AND MOLECULAR BIOLOGY OF AMINOGLYCOSIDE RESISTANCE IN NOSOCOMIAL INFECTIONS

J.F. John, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *109 Bee St., Charleston, South Carolina* 29403 (201-36-1416)

I am studying the epidemiology and molecular characteristics of antibiotic resistance (R) plasmids from aminoglycoside-resistant bacteria. Plasmids are visualized by agarose gel electrophoresis of ethanol-precipitated plasmid DNA. R plasmids are isolated by transfering them to sensitive recipients by conjugation or transformation. Aminoglycoside modifying enzyme activity is determined in the donors, transconjugants, and transformants. The project has concentrated on multiresistant Serratia marcescens (MRSM) the most common gentamicin-resistant Enterobacteriaceae in our hospitals. We have found 10 different conjugative R plasmids in MRSM thus far in Charleston. These plasmids have varying degrees of homology with one another as seen by analysis of DNA fragments from restriction endonuclease digestions. Our major findings include 1. A 6' amino-glycoside acetyl transferase (AAC) coded by chromosomal genes of amikacin-resistant S. marcescens. 2. An endemic 41 MD plasmid at Medical University Hospital originating in a neurological intensive care unit. This conjugative plasmid confers multiple antibiotic markers and elaborates either an AAC (3)-I or AAC (3)-III. MRSM containing the 41 Md plasmid has colonized or infected over 120 patients in the affiliated hospitals. 3. Plasmids at the Charleston VAMC differ in size from the Medical University plasmid types; 41 Md plasmids have not been found at the VAMC. Other Serratia plasmids, however, at VAMC exhibit varying degrees of homology with the 41 Md plasmid. 4. By comparing epidemiologic variables of MRSM-infected versus non-infected groups of patients in the same hospital location, no significant difference was found in antibiotic exposure, gentamicin exposure, pyuria, presence of bladder catheter, or length of hospital stay. 5. Other plasmids from gentamicin-resistant Enterobacteriaceae differ in size and restriction fragments from plasmids in S. marcescens.

GASTRIC LESIONS IN RHEUMATOID ARTHRITIS PATIENTS

P.H. Guth, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Gastroenterology Section, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (562-36-8405)

This is prospective endoscopic and biopsy (bx) study of the gastric and duodenal mucosa in rheumatoid arthritis (RA patients (pts) on long-term non-steroidal anti-inflammatory therapy. To date, 26 pts have had endoscopy and 16 also had multiple box of antrum and duodenum.

The patients with gastric ulcer (GU) were in the distal antrum or pyloric channel; most erosions were in the antrum. Duodenal changes were minimal except for 1 duodenal ulcer found in a pt with 3 GU. None of the pts with ulcers and only 3 with Gastric Erosions (ER) had symptoms. All 9 pts with GU/ER had histologic gastritis in the intact areas of mucosa, and 5 had intestinal metaplasia. In contrast, of 7 pts without GU/ER only 3 had gastritis and 1 had intestinal metaplasia.

The preliminary data suggest that in treated RA pts 1) symptoms were poor indicators of GU/ER, 2) Duodenal lesions were uncommon, and 3) There was a strong association between intestinal metaplasia and gastric ulcers and erosions.

3.1384,

THE DETECTION OF INTERMITTENT ACUTE PORPHYRIA IN PSYCHIATRIC POPULATIONS

B. Woodward, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Belmont St., Brockton, Massachusetts* 02401 (553-66-5771)

PROJECT OBJECTIVES: (1) To determine the frequency of intermittent acute porphyria (IAP) in Brockton VAMC psychiatric inpatients; (2) To identify patients with the disease for neuropsychiatric study.

PLAN: Uroporphyrinogen-I-Synthetase, the enzyme deficient in the disease, is determined qualitatively for all psychiatric inpatients. Patients with low enzyme levels have a quantitative enzyme assay and determination of urinary porphyrin precursors, which are elevated attacks of porphyria.

METHOD: Blood specimens obtained for admission and routine blood counts are frozen and transported to Dr. Tishler's laboratory at Harvard Medical School where the enzyme assays are performed. Positive results are followed up with quantitative studies and shared with the patients' physician. The investigators provide consultation, genetic counseling, and family studies to the extent requested by the patients' physician.

RESULTS TO DATE: Between December 1976 and February 1980, 1348 samples were screened. Seven were qualitatively positive and specimens for quantitative assay were obtained. Four were normal, indicating those patients do not have the disease. One was border line, and two were clearly within the porphyric range. Additional studies of urinary porphyrin precursors are now in progress to clarify the relationship of these findings to classical IAP.

CLINICAL RELATIONSHIP: The results indicate that ca. 0.2% of individuals screened have the enzyme deficit associated with IAP. They are at risk for life-threatening attacks of the disease. This frequency is much greater than the best estimates for the general population (ca. 0.002%), indicating a small but important number of hospitalized veterans may be at risk for acute attacks of IAP.

3.1385,

PROSPECTIVE EVALUATION OF PATIENTS WITH SUSPECTED SINUS NODE DYSFUNCTION

R.C. Dhingra, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Cardiology Section, *820 S. Damen Ave., Chicago, Illinois* 60612 (274-50-3879)

Seven patients had chronic, unexplained, nonparoxysmal sinus tachycardia. The clinical, electrocardiographic, and electrophysiologic characteristics of these cases are described. In each case electrocardiographic and electrophysiologic observations suggested that tachycardia was nonparoxysmal and due to increased automaticity of the sinus node (or of an automatic atrial focus located very near the sinus node). The mechanisms of increased sinus node automaticity in these patients were explored using drugs affecting the autonomic nervous system. In each patient these studies suggested a defect in either sympathetic or vagal nerve control of resting heart rate, with or without an abnormality of intrinsic heart rate.

Prolonged (greater than 152 msec) calculated sinoatrial conduction times (SACT) were found in 24 of 470 patients studied by the atrial extrastimulus technique, ranging from 155 to 220 msec (180 plus or minus 4.4; mean plus or minus SEM). There were 18 males and six females with ages of 29 to 85 (mean 65 plus or minus 2.6). Electrocardiographic monitoring revealed significant sinus or atrial dysrthythmias in 19 (79%) patients. Of these 19, 15 had persistent sinus bradycardia and/or sinoatrial block, three had sinus bradyarrhythmia with paroxysmal atrial tachycardia, and one had isolated atrial tachycardia. Additional electrophysiological evidence of sinus node or atrial dysfunction was present in 11 patients. Four patients needed permanent pacing during follow-up (mean follow-up period of 427 plus or minus 39 days) because of symptomatic bradyarrhythmia. Three patients died, none suddenly. In conclusion, prolonged calculated SACT was associated with a high incidence of electrocardiographic and electrophysiologic abnormalities of sinus node and/or atrium. Despite this, bradyarrhythmic morbidity was relatively low, suggesting that prolonged sinoatrial conduction time in the absence of symptoms is not an indication for prophylactic pacing.

GENETICS OF EPILEPSY AND EFFECTS OF ANTIEPILEPTIC DRUGS

B.A. Schaumann, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neurology Service, *54th St. & 48th Ave. S., Minneapolis, Minnesota* 55417 (468-66-6412)

This program consists of two projects: 1) A Genetic and Epidemiological Study of Epilepsy. This is an ongoing study of the role of genetic and environmental factors in seizure disorders and factors affecting prognosis of specific types of epilepsy. A total of 280 Minneapolis VAMC patients with confirmed diagnoses of epilepsy have been interviewed, clinically examined, and their medical records reviewed. subgroup of 46 patients with first-degree relatives suffering from seizures has been identified. These patients and their relatives (affected and unaffected) are undergoing further clinical testing. Interviews and testing will continue until sample sizes large enough for a meaningful statistical analysis have been obtained. 2) Cytogenetic Evaluation of the Effects of Anticonvulsant Drugs. The objective of this new project is to determine the effect of specific anticonvulsant drugs on human chromosomes in an attempt to elucidate a possible causative relationship of the reportedly elevated frequency of malignancies in epileptic patients and drug induced chromosomal damage. Studies of peripheral lymphocytes of long-term users of specific anticonvulsants (phenytoin, carbamazepine, phenobarbital and their combinations) have been initiated. Mitotic index depression, chromosomal breaks and aberrations and frequency of sister chromatid exchanges are being studied. Twenty-six patients have been studied to date.

SMOKING AND DIABETIC RETINOPATHY

A.M. Potts, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *800 Zorn Ave., Louisville, Kentucky* 40202 (282-26-0773)

The status of diabetic retinopathy as one of the principal causes of blindness in the U.S. is unchallenged. The question of whether cigarette smoking affects diabetic retinopathy is still an open one and needs investigation. The project is well within the scope of our capabilities and when recruitment difficulties are overcome, we expect to engage our full efforts in executing it.

A 20-YEAR STUDY OF NARCOTIC ABUSE IN TUCSON, ARIZONA

T.J. Cox, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Drug Dependence Treatment Program, *3601 S. 6th St., Tucson, Arizona* 85723 (527-38-6675)

This project is inactive because of non-funding by NIDA. Although the proposal was accepted on its scientific merit it was not given a high enough priority

for funding. One publication has resulted: 'A Twenty-Year Follow-Up of Narcotic Addicts in Tucson, Arizona,' Am J Drug Alcohol Abuse 6(1):25-37, 1979 (co-author, Peggy Harrington, M.S., Research Assistant). The following abstract is submitted as the final report: This preliminary report from an epidemiological study of heroin addiction in Tucson, Arizona, 1956-1957, examines the status of heroin addicts 20 years after they have been identified as narcotics abusers, focusing on the maturation hypothesis which holds that heroin addicts tend to cease use of narcotics spontaneously by age forty.

A cohort of 51 subjects was identified from Public Records of Court Appearances for narcotic offenses during a 36-month period (1955-1957), located and, where possible, interviewed. Records from a minimum of two agencies (law enforcement, corrections, treatment, welfare) were used to establish current status of the individual with reference to the use of narcotics and/or other drugs. Demographic, ethnic, socioeconomic makeup of the sample, as well as criminal involvement and treatment episodes, is included.

After 20 years, one individual is drug-free or abstinent. Twenty-three are considered still addicted to heroin, 16 of these are in prison; seven are addicted to methadone or alcohol. Thirteen are dead. Six could not be located; however, five could be traced well beyond 1956 through criminal activities. All but one person have passed their fortieth birthdays. For these 51 addicts, the maturation hypothesis does not hold.

STUDY OF TRANSIENT GASTRIC HYPOCHLORHYDRIA

C.T. Richardson, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Gastroenterology Section, *4500 S. Lancaster Rd., Dallas, Texas* 75216 (450-66-9086)

These experiments are designed to study spontaneous hypochlorhydria and gastritis. We are continuing to search for the cause of this phenomenon. We have developed a pepsinogen assay and will utilize this blood test to search for sporatic cases of hypochlorhydria. Preliminary studies have suggested that serum pepsinogen concentration increases as patients develop hypochlorhydria. Therefore, this test can be used to screen a large number of people. In addition, we will evaluate the epidemiology of this condition and will measure gastric acid secretion, serum gastrin concentration, and intrinsic factor concentration.

3.1390,
ROLE OF ESTROGENS AS A FACTOR IN CANCERS OF HEAD AND NECK

W. Guerra, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Togus, Maine* 04330 (119-05-7911)

The incidence of squamous cell cancer in head and neck is high among chronic alcoholics as supported by clinical and epidemiological evidence. Increased levels of plasma estrogen have been reported in alcoholic cirrhosis and chronic alcoholism. The elevated plasma estradiol was regarded as a possible common factor. Therefore, the object was to test for the presence of specific estradiol receptor proteins in this group of squamous cell cancer which appear to develop in a milieu of high estrogen plasma levels.

The plan involved assay of estrogen receptor in the cancer cells by thin layer gel filtration method after incubation with tritiated estradiol. High affinity binding of tritiated estradiol to specific receptor proteins could be determined in the presence of non-specific binding protein component. As little as 50 mg of tissue sample could be used.

METHODOLOGY: Cancer cells were disrupted by sonifier in Tris-EDTA buffer and centrifuged at 10000 g. Supernatant was incubated at 0 degrees C with (3H)17Beta-estradiol for 30 min. and then applied to Sephadex plated surface of the Pharmacia thin layer gel apparatus. Inclination of the plate effected the separation and the radioactive complex was transferred to filter paper. The dried samples were placed in a scintillation spectrometer and radioactive determination made. Appropriate controls were run.

Nine tumor biopsies were tested; specific binding ranged from 10-35.5%. This preliminary study shows evidence of estrogen receptors present in squamous cell tumors of head and neck.

3.1391,
THE EPIDEMIOLOGY OF MULTIPLE MYELOMA

H.J. Cohen, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *508 Fulton St., Durham, North Carolina* 27705 (054-32-0582)

This is a retrospective and prospective case control approach to the investigation of the epidemiology of multiple myeloma. Studies focus on occupation with particular emphasis on radiation and on details of socio-economic class and medical history. Approximately two-thirds of the data concerning the retrospective studied cases have been abstracted, as have about 15% of the control data. The expected number of cases have been interviewed prospectively, but only 1/6 of the intended controls have been completed. A number of interesting tentative findings have thus far been derived from the data. These include: 1) A four-fold increased risk of multiple myeloma in first order relatives 2) Familial aggregation of multiple myeloma and demyelinating disease syndromes resembling multiple sclerosis. 3) Possible association between multiple myeloma and occupational low level radiation. 4) No apparent association between multiple myeloma and high socioeconomic status or diseases of immunity, allergic disorders, or chronic infections.

The study is continuing with the expectation that the required number of cases in control abstracts will be completed within the next year and one half.

PREVALENCE OF PSYCHOSOCIAL PROBLEMS AMONG MEDICAL/SURGICAL INPATIENTS

T. Cornbleth, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *University Dr. C, Pittsburgh, Pennsylvania* 15240 (478-40-6666)

OBJECTIVES: (1) To assess the prevalence of psychosocial problems among medical-surgical inpatients; (2) To examine the distribution of psychosocial problems among patient subgroups; (3) To determine the extent to which patients who might benefit from mental health services are receiving these services; and (4) To evaluate the efficacy of using nursing personnel's routine observations for screening purposes.

PLAN: To survey a representative sample of VA Medical Center medical-surgical inpatients for whom mental health services might be provided.

METHOD: Questionnaire and interview.

RESULTS/CONCLUSIONS TO DATE: None.

MULTIPLE SCLEROSIS IN THE FAROES

J.F. Kurtzke, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neurology Service, *50 Irving St. N.W., Washington, District of Columbia* 20422 (133-16-2851)

As of September 1980, we have identified a total of 39 native-born Faroese with MS. They consist of A: 24 Faroese who had not been off the islands before onset (14 male, 10 female), B: 7 Faroese who had each been off the islands for a total of less than two years before onset (1 male, 6 female), and C: 8 Faroese who had been off the islands three or more years before onset (1 male, 7 female), four of whom also had onset outside the islands.

The native-born resident Faroese MS series is taken as A (24) plus B (7) for total of 31 cases (15 male, 16 female). The group of 8 with prolonged foreign residence is assumed to have acquired their disease off the Faroes.

Onset in Group A took place between 1943 and 1961 inclusive in 23 cases, plus one with onset in 1970. Onset in Group B took place between 1945 and 1973 inclusive: 3 before 1950, and 1 each in 1956, 1965, 1968, 1973. Onset in Group C ranged from 1917 to 1977.

The accepted series (A plus B) still follows a lognormal distribution compatible with the prior interpretation of a point source epidemic. There are now two patients born after WW II, with onsets in 1970 and 1968; both came from the same small area of the island of Eysturoy.

3.1394,
ZINC AND VITAMIN A LEVELS IN PATIENTS WITH ESOPHAGEAL CARCINOMA

T.O. Lipman, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *50 Irving St. N.W., Washington, District of Columbia* 20422 (116-34-5583)

Seventeen patients with squamous carcinoma of the esophagus and without gross evidence of malnutrition were evaluated for zinc and vitamin A nutriture, using plasma zinc and plasma vitamin A levels. Protein-energy nutritional status, hepatic status, and factors known to effect plasma zinc levels and plasma vitamin A levels were assessed. Three control groups were also evaluated: (1) chronic alcoholics without carcinoma; (2) non-squamous, non-lung carcinomas without alcoholism; (3) subjects without alcoholism or carcinomas.

Mean plasma zinc levels were significantly lower in the esophageal carcinoma group (65.7 plus or minus 2.3 ug/dl) than in the carcinoma group without alcoholism (77.4 plus or minus 3.6 ug/dl or the non-carcinoma, non-alcoholic group (80.5 plus or minus 2.4 ug/dl). Mean plasma levels in the esophageal carcinoma group did not differ significantly from the chronic alcoholic group (72.4 plus or minus 3.9 ug/dl).

Patient groups with both esophageal carcinoma and other non-squamous carcinomas had significantly lower mean plasma vitamin A levels (32.6 plus or minus 3.4 ug/dl and 43/6 plus or minus 4.1 ug/dl respectively) vs. mean plasma vitamin A levels in the alcoholic and non-alcoholic non-carcinoma groups (53.3 plus or minus 6.5 ug/dl and 60.2 plus or minus 4.2 ug/dl respectively).

Liver disease and protein-energy malnutrition were uncommon in any group. Our findings suggest a true deficiency of zinc and/ or vitamin in patients with esophageal squamous carcinoma. We hypothesize that this deficient state may contribute to the development of esophageal squamous carcinoma.

MONITORING OF CIMETIDINE INDUCED LEUKOPENIA

B.D. Danielson, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *Elm St. & 21st Ave. N., Fargo, North Dakota* 58102 (473-44-1195)

PROJECT OBJECTIVES: (1) To determine the incidence of leukopenia occurring in hospitalized patients treated with cimetidine; (2) to determine the effect of oral cimetidine versus the effect of intravenous cimetidine on white blood cells; (3) to determine if any relationship exists between cimetidine blood levels and the effects on white blood cells.

PLAN: Patients treated in their normal course of therapy with cimetidine will, if they so consent, have samples of blood drawn at set intervals for the purpose of analysis for complete blood counts, and blood level determination for cimetidine. These patients must have a baseline normal white blood cell count, not carry a diagnosis implicated with alteration of white blood cell counts, or be taking other medication known to cause alterations of white blood cell counts.

METHOD: Complete blood counts with differentials and cimetidine blood levels are within the capabilities of this hospital. Determination of the cimetidine blood levels will be made utilizing a derivation of the assay developed by Randolph and co-workers.

CLINICAL RELATIONSHIP: This area of research is extremely important in the safe treatment of patients treatment with cimetidine.

BODY COMPOSITION AND MORBIDITY IN AGING MEN

G.A. Borkan, U.S. Veterans Admin., Dept. of Medicine & Surgery, Outpatient Clinic, *17 Court St., Boston, Massachusetts* 02108 (149-38-6510)

PROJECT OBJECTIVES: 1) To develop an equation to predict fat-free mass and total fat in Normative Aging Study (NAS) participants. 2) To determine if body composition (especially fat-free and fat mass) was predictive of morbidity and mortality in this population over the past 15 years. 3) To evaluate a portable ultrasound machine for the measurement of subcutaneous fat and muscle thickness.

PLAN: Anthropometric and health data are available for 2260 initially healthy Normative Aging Study participants for 15 years. To improve available body composition data, special examinations of 200 participants will be made to determine a predictive equation for total fatness and to evaluate the ultrasound equipment. Data analysis will relate specific body composition measures to 30 major disease types, self rated health and mortality.

METHODOLOGY: Special body composition evaluations will include measurement of total body potassium in a whole body counter (VA Medical Center, Boston), anthropometry (standard NAS test battery), ultrasound (Body Composition Meter, Ithaco, Inc., Ithaca, N.Y.). Ultrasound accuracy testing will be made on cadavers at Harvard Medical School.

CLINICAL RELATIONSHIP: This research is relevant to issues of preventive medicine and dietetics. Results may indicate the extent to which body composition predisposes to specific diseases, and have bearing whether weight loss or gain may be an effective preventive measure.

GROUP B STREPTOCOCCAL INFECTIONS IN THE NEWBORN

L.J. Fenton, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neonatal Biology Section, *Sioux Falls, South Dakota* (295-36-4274)

Epidemiological aspects of Group B streptococcal (GBS) infection and specific properties of the GBS were investigated for this final year of the grant. An analysis of factors which predisposed to maternal colonization revealed that the use of estrogen pills prior to conception, maternal fever, and endometritis were significantly correlated with fever at delivery, vaginal delivery and a prolonged second stage of labor. The external auditory canal and umbilicus were the best sites for recovery of GBS in the infant; while vaginal, rectal and periurethral suds were equally satisfactory in the mother. Todd-Hewitt Broth containing colistin and nalidixic was found to be an excellent selective medium and did not require blood for good recovery. CIE was only able to detect GBS in 50% of maternal cultures when applied directly to the initial broth containing mixed flora. There were no false positives, however. The function of the alternative pathway of was found to be mildly but significantly correlated with birth weight and independent of maternal illness. The hyaline membranes in babies who died from GBS sepsis and pneumonia and those who died in the first few days from IRDS were found to contain C3, IgG, C4 and factor B. A common inflammatory pathway is suggested with possible immune injury to alveoli. Finally, an endotoxin-like property was attributed to the GBS based on clinical, in vivo (animal) and in vitro studies.

INTRAHOSPITAL TRANSFER OF PLASMIDS ENCODING FOR MULTIPLE ANTIBIOTIC RESISTANCE

J.J. Plorde, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Infectious Disease Section, *4435 Beacon Ave. S., Seattle, Washington* 98108 (476-32-6618)

Our previous studies had documented that an epidemic of urinary tract infection at the Seattle Veterans Administration Hospital was caused by the spread of both an epidemic bacterial strain (Serratia marcescens) within the hospital and the spread of a single 45 Md plasmid to a variety of other Enterobacterizciae.

In the past year we have examined 165 new strains of gentamicin resistant Enterobacterizciae to determine whether or not gentamicin resistance in the post epidemic period was still mediated by this single plasmid. Twenty-one different species were included in the study. Sixty-four belonging in 9 species harbored the same plasmid. Forty-seven isolates of 4 species including two organisms from other institutions carried as 12 Md plasmid. Eleven isolates belonging to 3 species carried a 105 Md R factor. We are now in the process of characterizing these plasmids more completely to define whether or not they represent the introduction of new R factors into our hospital or the 'evolution' of our epidemic plasmid through the acquisition of resistance carrying transposons.

We have also initiated a prospective study of catheterized urology patients to determine the frequency of in vivo R plasmid spread within this unique population. To date we have examined 116 urine specimens from 31 patients. In one patient we have been able to demonstrate the spread of an R factor encoding for gentamicin resistance from a strain of Citrobacter freundii to three other specimens of Enterobacteriaciae isolated sequentially from his urine.

3.1399,

THE EFFECT OF RETIREMENT ON PHYSICAL HEALTH

R. Bosse, U.S. Veterans Admin., Dept. of Medicine & Surgery, Outpatient Clinic, *17 Court St., Boston, Massachusetts* 02108 (020-22-8564)

OBJECTIVES: to examine possible changes in physical health related to occupational retirement and to detail the nature of these changes and the circumstances under which they occur.

RESEARCH PLAN: The study population consists of 900 males (aged 50 plus in 1975) who are participants in the Normative Aging Study. The population is divided into two groups: (a) 380 men working at baseline physical examination but retired at follow-up exam; (b) 520 men employed at baseline and at follow-up exams. Retirees and their working age peers will be compared for differential patterns of health change while controlling for intervening variables such as education, income, occupational type and attitudes toward work and retirement. In addition, the investigation will specify health change as to type of morbidity and examine whether changes in physical health are more prevalent at any particular time following retirement.

METHODOLOGY: Health status at baseline and follow-up (3 years apart) is assessed by self-report and by physical examinations. Physical exam data were available from the parent study, as were data from a pre-retirement questionnaire on work situation, health and lifestyle. Follow-up data on the work and retirement situations of the two groups were collected in the past year.

FINDINGS: There is no excess incidence of decline in self-assessed health among retirees compared to age peers who continue to work. Neither does retirement prompt any increase in the frequency of somatic complaints. Health reversals are no more prevalent during any particular interval over the first three years after retirement.

SPONTANEOUS BACTERIAL PERITONITIS

A.S. Barritt, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Gastroenterology Section, *Salem, Virginia* 24153 (099-40-9819)

This project was conceived to look prospectively at patients with cirrhosis of the liver and determine the incidence of a specific complication - spontaneous bacterial peritonitis. The only procedure involved is an abdominal paracentesis, and there have been no complications in the 50 patients entered so far. The incidence of peritonitis is 6% to date.

Original plans were to include at least 50 patients. Because the incidence of peritonitis has increased in the second year of the study, I plan to continue to a total of 100 patients. There were 0 cases of peritonitis in 20 patients during the first year and 3 cases in 30 patients during the second year.

PROGRESS REPORT: Since the last report there has been one case in 24 patients. The data will be collected and reported shortly.

3.1401,

PATHOGENETIC ROLE OF CRYOGLOBULINS IN RENAL DISEASE (C.I.G.)

J.J. McPhaul, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Hemodialysis Unit, *4500 S. Lancaster Rd., Dallas, Texas* 75216 (577-36-8915)

OBJECTIVES OF PROJECT: A) To survey the nephritic population to define 1) incidence, 2) composition, 3) magnitude and 4) immunologic reactivity of C.I.G. patients among those with documented renal disease. B) To define the potential immunologic relationship between C.I.G. and mechanism of renal injury in such patients. C) To define the immunological relationship between C.I.G. and circulating immune complexes in patients with presumed immune-complex glomerulonephritis.

RESULTS: Previous report of 8/78 described survey results for C.I.G. in patient groups, and anti-Ig activities of the isolated cryoprecipitates (CP). The latter also were tested for autoantibody and antigen content. For antibodies: 7 solubulized CP were incubated with homologous tissue sections and tested for Ig binding by immunofluorescence (I.G.); 3/7 had significant content of antibodies (1 each to vascular smooth muscle, cardiac muscle, and skeletal muscle). For antigen content: rabbits were immunized with CP emulsified in complete Freund's adjuvant, and antisera absorbed with normal human serum (idiotypic antisera) were tested for binding to human tissue sections; 4/19 antisera had binding activity (to skeletal muscle, nuclei, reticulin, and elastin respectively). To establish an immunologic relationship between CP and immunoglolin (Ig) deposits seen in patient kidneys by I.F., fluorescent idiotypic antisera were tested on autologous kidney sections; 1 antiserum to CP also bound to autologous immune deposits. These data suggest that C.I.G. occurs in small fraction of patients with renal disease. When it occurs, the CP often contain definable autoantigens and/or antibodies. In only 1 of 10 cases was it possible to show an immunological identity between renal Ig deposits and the isolated CP.

AMERICAN HEALTH FOUNDATION EPIDEMIOLOGICAL STUDIES

N. Spritz, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *1st Ave. at E. 24th St., New York, New York* 10010 (215-24-4788)

Tobacco-related cancers and myocardial infarction continue to constitute a major source of death and disability in the U.S. (deaths and morbidity which largely are preventable because of their association to tobacco usage). Collection of data on smoking habits, demographic characteristics, alcohol consumption, occupational and medical histories of patients with tobacco-related diseases and matched controls continues. Annually, 300 lung, esophagus, and bladder cancer patients plus 300 first episode myocardial infarction and 150 pancreatic cancer patients will be interviewed. Results indicate that the risk of developing these diseases increases with quantity smoked, duration of the habit and, for lung and larynx cancer, non-filter cigarette smoking. Risk of mouth, larynx and esophagus cancer among smokers increases with quantity of alcohol consumed. Increased smoking and low cessation rates are noted among lower socioeconomic groups suggesting that these groups will bear an ever increasing proportion of the burden of tobacco-related diseases.

Collection of data (on demographic characteristics, diet and lifestyle habits) in patients with gastrointestinal tract cancer and control patients continues. To date we have 799 gastrointestinal tract cancer cases and an equal number of controls. Fifty percent of the cases have primary colon cancer, 18% have primary rectal cancer, 16% have primary gastric cancer, and 12% have intestinal polyps.

A preliminary analysis of demographic variables and dietary factors has been performed, and a paper is in preparation.

PSYCHIATRIC ILLNESS ON MEDICAL AND SURGICAL WARDS - FOLLOW-UP OF A PROSPECTIVE

J.D. Berman, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *3350 La Jolla Village Blvd., San Diego, California* 92161 (032-42-2894)

The proposed investigation represents a two-year follow-up of a study in which 300 medical surgical patients, ages 65 and over, were evaluated by means of a structured psychiatric interview for the presence of diagnosable psychiatric illness. A substantial rate of previously unrecognized psychiatric illness was found. The present proposed study will establish prognostic implications for various psychiatric diagnoses in patients of this age group and also compare the prognoses of the medical illnesses in these patients in the presence and absence of psychiatric illness.

STUDY ON THE EPIDEMIOLOGY OF CRYPTOCOCCUS NEOFORMANS

J.W. Brandsberg, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Leavenworth, Kansas* 66048 (503-32-2824)

Cryptococcus neoformans has been known since 1894 when Sanfelice discovered it in peach juice and demonstrated that it caused lesions in experimentally infected animals. It was first isolated antemortem from a case of cryptococcal meningitis by Verse in 1914. No source of infection was known until 1955, when Emmons reported finding it regularly in pigeon nests and droppings under pigeon roosting sites. No one has yet shown how the yeast gets into the pigeon habitat although there is considerable information relating to how it survives and reproduces in weathered pigeon droppings. Preliminary studies have suggested that the bird's feed may be the source, although C. neoformans has not been found in food materials commonly fed to domesticated pigeons; however, other species of Cryptococcus are commonly found in bird feeds. The object of this study is to attempt to determine the source of C. neoformans in pigeon droppings - a very basic aspect of the epidemiology of cryptococcosis. This is to be accomplished by examining various feed materials available to domestic and wild bird flocks in this area and using a variety of methods to isolate and characterize any C. neoformans present. Pathogenicity, physiology and mating types of these will be compared to isolates obtained locally from wild bird roosting sites.

PROSPECTIVE SEROLOGIC STUDY OF LEGIONNAIRES' DISEASE IN FAMILIES

M.J. Gunwith, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Infectious Disease Section, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (488-40-9291)

The hypotheses is that the clinical and epidemiologic features of Legionnaires' disease can be better understood by studying sera obtained from a family study of diarrhea and respiratory disease, where the sera and clinical data have already been prospectively obtained. The families are from both rural and urban Canada. Serologic conversion and antibody levels to Legionella pneumophila will be measured, using the IFA technique, with the four known serotypes of L. pneumophila as antigens.

VALIDATION OF SURVEY OF DRINKING BEHAVIORS AMONG VA OUTPATIENTS

K.M. Habib, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Health Services Research, *Raleigh Rd., Fayetteville, North Carolina* 28301 (217-48-0825)

The results of this study give two independent estimates of alcoholism in the VA outpatient population which are significantly different from each other. In all of the study hospitals, the MAST gave a consistently higher prevalence than clinical judgments.

We examined a number of factors which we felt might explain some of the differences in the two estimates, however, we failed to show a consistent relationship for any of these factors. It is concluded that VA clinicians in general have a higher threshold for judging alcoholism than does that MAST.

Other factors which one might wish to consider in choosing one methodology over the other have more to do with administrative difficulties than with scientific validity. For example, in the study hospitals it generally took less time to train four to five MAST interviewers than it did to mobilize clinical staff to participate in the study. Another consideration is that the MAST took up more patient time (about 8-10 minutes per patient on the average) but the clinical judgment took up more physician time. Important from a research point of view is that patient compliance is better than clinician compliance resulting in higher response rates. In general the weight of these administrative considerations, combined with the fact that the MAST is more uniform and objective than the clinical judgements, tends to favor the use of the MAST in situations where only one method for determining alcoholism is needed.

COMPUTER ANALYSIS OF MICROBIOLOGIC DATA

M.L. Spivack, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Infectious Disease Section, *150 S. Huntington Ave., Boston, Massachusetts* 02130 (045-22-8382)

The programs for entrance of microbiologic data into the H-P 9830 computer were completed in May, 1978. All organisms isolated in the Microbiology Laboratory on which antibiograms were done have been entered on a daily basis since that time. Retrieval programs for analysis of data from the H-P 9830 A were being developed and a number were in use until February, 1980, at which time a decison was made to purchase a DEC-MINC-11 computer to be used for direct entrance of data by the microbiology technicians. A part of this project involved the use of a digitizer to directly read zone diameters. It is expected that this aspect of the project will be completed shortly and that retrieval programs will then be written to extract data of epidemiologic interest.

DEPRESSION AMONG HYPERTENSIVES AND IMPLICATIONS FOR PATIENT ADHERENCE TO ANTI-HYPERTENSIVE MEDICATION

P.M. Albertoli, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *W. Spring St., West Haven, Connecticut* 06516 (049-48-2743)

The study outlined in the proposed research will examine the inter-relationships among hypertension, depression, and patient adherence to anti-hypertensive agents. Depression will be examined as it relates to pre-morbid affective history, medication and side effects, demographics, compliance, degree of hypertension and electrolyte status. Measures of depression, medication side effects and compliance will be combined in questionnaire. An interview measuring present affective status and past affective history will also be done.

Data will be collected over a six week period in an outpatient hypertension clinic; sixty subjects will be involved in this study.

A primary goal of this study is to provide information which is intended to be of value to the nursing practitioner in facilitating the effective emotional and medical management of the individual with hypertension.

DURATION OF OROPHARYNGEAL COLONIZATION WITH GRAM-NEGATIVE RODS IN HOSPITALIZED PATIENTS

C.J. Schleupner, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Infectious Diseases Section, *Salem, Virginia* 24153 (220-42-6907)

The oropharynx of healthy individuals is not usually colonized with Gram-negative Bacilli. Among hospitalized patients, 60% or more of individuals may become colonized during hospitalization. This colonization may subsequently lead to the development of Gram-negative rod pneumonia. Numerous previous studies have evaluated the frequency and chronology of acquisition of Gram-negative rod colonization but have not evaluated the duration of such colonization. It is the aim of our study to further our understanding of the epidemiology of Gram-negative rod colonization by following a group of hospitalized patients who become colonized during hospitalization for the duration of their colonization. We hope, by clarifying the relationship of the factors associated with acquisition of Gram-negative rod colonization to the duration of this colonization, we will be able to further understand host-parasite interactions. Our research plan will be to follow a group of 50 patients who acquire Gram-negative rod colonization during hospitalization to determine the duration of their colonization. Various clinical factors and measures will be recorded to develop relationships between the duration of colonization and a patient's clinical status. Patients will be followed after discharge from the hospital in order to allow for appropriate follow-up.

As of this date, only four to five patients have been enrolled in the study, but it is anticipated that the entire project will be able to be completed before the end of this summer.

DELAYED STRESS DISORDER IN HISPANIC VIETNAM VETERANS

R.L. Hough, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (525-72-4740)

The objectives of this research study are (1) to develop and validate measures of Vietnam-linked Post Traumatic Stress Disorder (VLPTSD) for use in Hispanic County populations; (2) to estimate the prevalence of VLPTSD among Hispanics in County Mental Health Catchment Area 100 (East Los Angeles); (3) to estimate the prevalence of other psychiatric disorders and socio-emotional adjustment problems in the same population; (4) to clarify the relationship of VLPTSD and other forms of psychiatric disorder and socio-emotional adjustment problems in the same population; (5) to examine the accuracy of several theories concerning variables associated with VLPTSD in the same population; (6) to determine if a model incorporating the various theories is significantly predictive of VLPTSD; (7) to explore dynamics of the elements of VLPTSD and its relationship to other forms of impairment and to successful life functioning via extended clinical interviews; (8) to test the relative efficacy of a three-stage clinical treatment developed by the East Los Angeles VA Neighborhood Mental Health Clinic, the usual group rap therapy, and other experimental model(s) developed from the results of this study for use with Hispanic victims of VLPTSD.

Methodology includes survey, interview and experimental therapy techniques. On the basis of the results of the data analysis, an experimental treatment plan will be piloted and evaluated in the third year.

EPIDEMIOLOGIC CATCHMENT AREA-LOS ANGELES, HISPANIC/ANGLO STUDY

R.L. Hough, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (525-72-4740)

The purpose of the proposed research is to (1) estimate the true incidence and prevalence of specific mental disorders according to current diagnotic criteria, using a sample survey of the general adult Hispanic and Anglo population, including those resident in institutions, from Catchment Areas 89 and 100 of Los Angeles County, (2) to study the factors associated with the development and continuance of these

disorders, and (3) to study the relationship between psychiatric disorder and utilization of psychiatric, general health, and other treatment facilities.

EPIDEMIOLOGIC SURVEY OF NON-A NON-B HEPATITIS IN A HEMODIALYSIS UNIT

E.D. Hendler, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Dialysis Unit, *W. Spring St., West Haven, Connecticut* 06516 (213-56-4729)

During the last 2 years we have detected 20 patients in the Dialysis Unit who presented with unexplained liver enzymes elevation and were diagnosed as having non-A non-B hepatitis. We are analyzing the presently available clinical data on our patient population and dialysis unit staff. To complete this initial survey we plan to ask the wives, and other relatives of those patients, living in the same household to complete a questionnaire and have blood drawn, once, to measure SGPT, SGOT, HBsAg and anti-HBs antibody. Although this information is needed clinically, we will also use it as a pilot survey to consider the need for a larger study on the clinical, epidemiologic and biochemical aspects of non-A non-B hepatitis to be proposed and conducted in the future.

3.1414,
DRINKING HISTORY OF ALCOHOLICS

A.S. Wilson, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *5000 W. National Ave., Wood, Wisconsin* 53193 (073-28-1036)

PROJECT OBJECTIVES: A large number of studies have in recent years tested hypotheses regarding factors that may differentiate alcoholics from nonalcoholics. Some of the studies have explored metabolic factors, personality factors, ability to discriminate blood alcohol level, amount of alcohol ingested per sip, etc. Surprisingly, nobody has bothered to look at what alcoholics drink and why they drink it. In other words, after so many years of research we don't have answers to questions such as: Do alcoholics drink more brandy than vodka? If so, it is because brandy tastes better, or is less expensive, or why? What are the favorite drinks of alcoholics? When they don't ingest alcoholic drinks, what do alcoholics drink?, etc.
RESEARCH PLAN: We are proposing that we gather information from alcoholics that will allow us to determine whether there is any pattern to the drinking behavior of alcoholics. For this purpose, we plan to distribute a questionnaire to both inpatients and outpatients currently under treatment for alcoholism at the Wood VAMC. The questionnaire was developed by Dr. Timothy Baker of the University of Wisconsin-Madison.
METHODOLOGY: See above.
FINDINGS: Not applicable.

3.1415,
SMOKING EFFECT OF LIPROPROTEIN LEVELS AND VASCULAR DISEASES

P. Mandelstam, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Leestown Pike, Lexington, Kentucky* 40507 (007-24-5900)

The key role of the plasma lipoproteins in the development of occlusive vascular disease is well known. Epidemiologic studies have implicated heavy and sustained cigarette smoking as an important risk factor in the development of atheromatous disease.
OBJECTIVES: 1. To ascertain whether cessation of smoking results in changes in serum cholesterol-binding reserve and in plasma lipoproteins (especially the high density lipoproteins) and whether resumption of smoking has any effect upon these components. 2. To determine in four groups of individuals (those free of vascular disease, those with coronary artery disease, those with peripheral arterial disease and those with carotid artery disease) whether or not smokers in comparison with nonsmokers and ex-smokers have altered serum cholesterol-binding reserve and altered plasma lipoproteins (especially the high density lipoproteins). 3. To determine whether cigarette smoking influences the frequency and severity of diabetic retinitis and to study the interrelationships between cigarette smoking, frequency and severity of diabetic retinitis and levels of plasma lipoproteins and cholesterol-binding reserve.
METHODS: Plasma will be utilized for lipoprotein electrophoresis and for preparative ultracentrifugation for the separate analysis of the high density, low density and very low density lipoproteins by standard methods. Cholesterol and triglyceride will be analyzed by standard methods; cholesterol-binding reserve by the method of Hsia.

3.1416,
YOUNG SUICIDES - A PSYCHIATRIC & TOXICOLOGICAL STUDY

R.C. Fowler, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *3350 La Jolla Village Blvd., San Diego, California* 92161 (480-46-3078)

OBJECTIVES: The suicide rate for young adults has been increasing. Concurrently, drug and alcohol use has also increased in this age group. In order to study the association between these observations, we are asking: (a) what are the types and frequencies of psychiatric disorders (including alcohol and drug related ones) in young suicides; (b) what alcohol or drug residues can be detected in the body after the suicide act; (c) are there diagnostic differences between the young suicide and the age 30 or older suicide; (d) is the veteran population over-represented in either age group; (e) are there psychological or pharmacological treatment differences between patients who suicide and living patients with the same disorder.
PLAN AND METHODOLOGY: Psychiatric assessment will utilize information from personal interviews with friends, family and treating health professionals, as well as Coroner's reports and an extensive toxicologic report. Structured interviews will be utilized and diagnosis will be assigned according to both the DSM-III and the more stringent Feighner criteria. We anticipate studying 150 suicides in the under 30 group and an equal number in the over 30 group. Collection of information on suicides is expected to take two years. The San Diego Country Coroner's office is collaborating in this phase of study. In order to look at effectiveness/adequacy or treatment, a control group of living patients matched for age, sex, socioeconomic status and diagnosis will be studied utilizing available records and drug/alcohol screens; interviews will not be done with the living subjects or family/friends in order to avoid comparability problems.

LONG-TERM STUDY OF CLIMATE EFFECT ON ASTHMA

D.J. Salberg, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Allergy Immunology Section, *Southfield & Outer Dr., Allen Park, Michigan* 48101 (334-36-1387)

Asthmatic attacks are often unpredictable and frequently cannot be related to a definite causal factor. Changes in climate have been reported on occasion to cause epidemics of acute asthma attacks. This study will follow a large population of patients having asthma and will attempt to correlate asthma attacks with changes in humidity, barometric pressure, temperature, wind speed and direction and pollutants as these conditions are recorded daily by the Federal government. Hopefully, further knowledge about the inter-relationship of asthma and climatic conditions will result from this study.

ETIOLOGY OF AORTIC INSUFFICIENCY - ASSOCIATION WITH ANKYLOSING SPONDYLITIS

Z.U. Hassan, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *1201 Broad Rock Rd., Richmond, Virginia* 23249 (180-36-1036)

The objectives of this study are 1) to determine the prevalence of ankylosing spondylitis and its variants such as spondylitis associated with psoriasis, Reiter's disease and inflammatory bowel disease in unselected cases of lone aortic incompetence, 2) to determine the prevalence of HLA-B27 antigen in these patients with lone aortic incompetence, and 3) to classify and define the spectrum of disease seen in association with lone aortic incompetence today. The study population will consist of patients with lone AI detected by a cardiologist by physical examination and confirmed by echocardiography or cardiac catheterization. Lone AI is defined as AI no accompanied by any other significant valve lesion (e.g. aortic stenosis, mitral stenosis or mitral insufficiency). These patients will be evaluated by a rheumatologist for possible etiology with special emphasis on symptoms and signs suggestive of ankylosing spondylitis and its variants. In addition to clinical rheumatological examination, the special studies will include serological tests for syphilis, rheumatoid factor, and HLA-B27 antigen. Radiological examination of sacroiliac joints and lumbosacral spine will be done when indicated by history, physical examination or a positive HLA-B27. Histopathologic examination of aortic valve and aorta will be done when the tissue is available following surgery or autopsy. Results will be tabulated to determine the prevalence of various diseases detected by this examination in our study population.

3.1419,
PERIPHERAL NEUROTOXICITY AT THE LOVE CANAL AREA OF NIAGARA FALLS, NEW YORK

S.A. Barron, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *3495 Bailey Ave., Buffalo, New York* 14215 (027-32-0164)

In Spring 1978, it was revealed that residents of the 'Love Canal' area of Niagara Falls, New York had been chronically exposed to industrial chemicals that had leaked from underground disposal sites into their homes. The 'Love Canal' has become a nationally recognized prototype of industrial environmental contamination. The present nerve conduction study was undertaken to detect evidence of toxic peripheral neuropathy as a result of that contamination. In a cohort study design, volunteers were screened for factors known to affect nerve condition. Thirty-five of two hundred volunteers passed the screening process. Controls were drawn from the neighboring census tract and twenty volunteers were eligible. The following was found to characterize the resident group: Slower sensory conduction velocity, the sural nerve showing the most prominent change. We suggest that nerve conduction techniques can serve as epidemiologic tools investigating health effects of certain types of environmental contamination.

THE EFFECT OF IODINATED CONTRAST MEDIA ON THE RENAL FUNCTION OF THE GERIATRIC PATIENT

E. Lozada, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *800 Poly Pl., Brooklyn, New York* 11209 (056-44-3760)

PROJECT OBJECTIVES: (1) To determine the effect of hypaque or iodinated contrast media on the glomerular and tubular function in the elderly population. (2) To determine the exact prevalance for renal failure in the geriatric group associated with IVP. (3) To shed light on the pathogenesis of iodinated contrast induced acute renal failure.
METHODS: A prospective evaluation of the effect of intravenous hypaque on the renal function of 100 geriatric patients undergoing IVP in St. Albans is currently being done to determine the effects of hypaque on glomerular and tubular function in the elderly population. Blood determination are being done for CBC, BUN, FBS, uric and creatinine and electrolytes. Urine studies for urine volume, creatinine, electrolytes, uric acid excretion as well as specific gravity and osmolality are being measured. Both urine and blood studies are being done 24 hours before and 24 hours after the injection of hypaque. Weights will be observed to determine the role of volume depletion on the pathogenesis of the acute renal failure. The results of the renal function will be adjusted to the expected age related decline in renal function.
CLINICAL RELEVANCE: Clinical information that will be obtained would be of tremendous help not only to the VA patients but for other patients as well.

3.1421,
ETIOLOGY AND EPIDEMIOLOGY OF LEGIONNAIRES' DISEASE

R.I. Wise, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Togus, Maine* 04330 (465-01-2392)

Recognition of infections caused by Serogroup 2 of Legionella pneumophilia, (Togus Strain) has been accomplished in 1979 with support of laboratories of C.D.C. Surveys for the presence of the bacterium in water from many sources have revealed viable L. pneumophilia in water specimens of shower heads in

building 207, but not in building 206 or 200. The Philadelphia Strain, Serogroup 1, was isolated from the water of shower heads and not Serogroup 2. Epidemiologic investigation of the presence of viable microorganisms in potable water are now in progress.

PHARYNGEAL FLORA

C.H. Ramirez Ronda, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *GPO Box 4867, Hato Rey, San Juan, Puerto Rico* 00936 (582-92-1553)

PROJECT OBJECTIVES: To study the pharyngeal flora by quantitative methods of house staff members over an 11-month period. To correlate the colonization with service rotation, viral illness and other variants.

PLAN: House staff members were requested to voluntarily participate in the study. Eighty-nine volunteered. The participants underwent quantitative pharyngeal cultures at weekly, bi-weekly or monthly intervals.

METHODS: Every participant underwent quantitative cultures using saline gargle. A total of 605 cultures were taken. Participants with upper respiratory infections (URI) were requested to provide blood for viral serologic studies. The colonization of the pharynx with gram-negative bacilli (GNB) and S. aureus (SA) was correlated with episodes free of illness and during episodes of viral URI.

RESULTS: Twenty percent of the house staff studied had 1 or more GNB in their pharynx during the study. Colonization by Sa was 8-9 percent, there was no difference in colonization between sexes, smoking habits or dental hygiene. Colonization was transient and lasted two weeks. During an episode of URI the colonization increased from 20 percent to 65 percent for GNB and from 8 percent to 38 percent for SA. High colonization rates were found also in this group of patients (Current Chemother Infect Dis II: 1011-1013, 1980).

CLINICAL RELATIONSHIP: The increased colonization of the pharynx with SA and GNB during URI may be related to the etiology of pneumonias.

A SURVEY OF LIP CANCER AND SOLAR CHEILOSIS IN THE STATE OF OKLAHOMA

S.K. Young, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Dental Service, *921 N.E. 13th St., Oklahoma City, Oklahoma* 73104 (487-52-5708)

OBJECTIVES: The purpose of this study is to study the relationship of sun exposure and solar cheilosis with the carcinogenesis of lip cancer in the state of Oklahoma.

RESEARCH PLAN: The VA Medical Center, Oklahoma Memorial and Presbyterian Hospitals will provide the sample population for this study. The study will be a retrospective study utilizing selected patient information obtained from the Tumor Registry, University of Oklahoma Health Sciences Center.

METHODOLOGY: Information needed will be obtained by review of patient charts and by telephone interview. Also involved will be a review of pathological biopsy slides for determination of changes indicated by solar radiation.

SIGNIFICANCE: What the investigators hope to discover is a correlation between the neoplasia experience and occupational information provided by the patient.

STATISTICAL MODELS IN HEALTH SERVICES RESEARCH - LOGISTIC REGRESSION WITH RANDOM EFFECTS

J.P. Krischer, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Health Services Research & Development Center, *Gainesville, Florida* 32601 (266-86-5654)

Many problems in health research involve the relationship between dichotomous response (indicating presence or absence of a certain characteristic) and certain factors. If the levels of a factor observed in the study group constitute a random sample of the levels contained in the population, then the factor is said to be random. Statistical methodology is not presently equipped for the analysis of dichotomous response models involving random factors.

The objective of this project is to develop a unified approach for the statistical analysis of the above types of models. Two such approaches that will be explored in great detail are:

1) 'heirarchical-Bayesian' -here it is assumed that the levels of the random factor vary according to a probability distribution which is naturally conjugate to the conditional distribution of the response.

2) logistic regression-here the logit transformation is applied to observed proportions and expressed as a linear model in the factors. Variation in levels of a random factor corresponds now to a Gaussian perturbation of the logit.

Computer analysis will help to determine the efficacies of these two approaches.

A PILOT CASE CONTROL STUDY OF SARCOMAS AND CHRONIC METALLIC FOREIGN BODY EXPOSURE AMONG WWII VETERANS

J.C. Lentz, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Raleigh Rd., Fayetteville, North Carolina* 28301 (229-80-1951)

Since the pioneering work of Turner and Oppenheimer et al. in which rats implanted subcutaneously and intraperitoneally with plastics were found to develop higher rates of sarcomas, similar research by a number of independent investigators has firmly established the role of foreign bodies in tumorigenesis in animals. Foreign body (FB) tumorigenesis in man has received little attention. Information concerning humans exists in the form of scattered reports in the literature on cancers developing at the sites of scars or FB. One possible population for the study of FB tumorigenesis in man is the combat veteran population of WWII. This group contains many individuals who for one reason or another have had combat related metal fragments and scars in their bodies for over 30 years. Also, it is a large group by epidemiologic standards, a fact which facilitates the study of low incidence neoplasms such as sarcomas. Furthermore, this group is typically cooperative in VA related interview research. The actual study design would call for the comparison of exposure information on 100 to 450 sarcoma cases and a similar number of controls. Criteria for selection would include histological verification of disease status and active service in the army or marines during WWII. Apart from providing important biomedical information on the likelihood of FB tumorigenesis in man, the results of this study, if positive, could suggest increased clinical suspicion for sarcomas and thereby lead to earlier detection and reduced mortality. This pilot project will be carried out with a very limited budget.

3.1426,
TRENDS IN THE INCIDENCE OF ISCHEMIC HEART DISEASE

B.R. Gelbaum, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *3495 Bailey Ave., Buffalo, New York* 14215 (121-22-3884)

The VA (Washington, D.C.) office provided a run on the numbers of first discharge diagnoses in the ICD8 code regions 410-414. The data were sorted by age groups in decades starting at age 18, by sex and by year starting in early 1972.

Preliminary analyses suggest that the trend in the incidence of ischemic heart disease in the population treated in VA hospitals is downward. The average decline in about eight years is about 40 percent in most age groups.

3.1427,
EPIDEMIOLOGICAL PATTERNS OF NASAL AND CUTANEOUS COAGULASE POSITIVE STAPHYLOCOCCI AMONG HEMODIALYSIS PATIENTS AND PERSONNEL

S.E. Goldblum, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *2100 Ridgecrest Dr. S.E., Albuquerque, New Mexico* 87108 (167-38-7679)

Infections are the second leading cause of mortality among hemodialysis (HD) patients. The majority of these infections are caused by S. aureus and are usually associated with the vascular access site. Therefore, the source of staphylococci and their pattern of carriage within the HD unit might offer therapeutic possibilities.

Skin contact and nasal swab cultures have been performed on approximately 50 chronic HD patients and 22 HD personnel at least once weekly over 24 weeks. All S. aureus isolates have been saved in a viable state. We wish to study the pattern of nasal and cutaneous staphylococcal carriage over the six months duration on both HD patients and HD personnel and any potential relationship between the staphylococcal carriage in either the HD personnel or patient groups and staphylococcal isolates appearing over the vascular access sites of HD patients. The specific, definitive identification of staphylococcal isolates will be determined by their susceptibility to standardized bacteriophages and their acquisition of resistance to antibacterial substances.

STUDY OF CHRONIC STRONGYLOIDIASIS IN WORLD WAR II PACIFIC THEATER PRISONERS OF WAR

L.L. Pelletier, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *American Lake, Tacoma, Washington* 98493 (160-38-3642)

The project was initiated on 5-8-80 after approval of the Research and Development Committee. Three-hundred and eighty six (386) questionnaires were sent veterans identified as former POWs by the Washington State POW organization. Two-hundred and sixty two (262) responses were received - 157 from former Pacific Theater ex-POWs. One-hundred and fifty five (155) Pacific Theater ex-POWs expressed willingness to participate in the study. Forty-four (44) individuals who indicated suggestive skin or gastrointestinal symptoms were examined in clinic. At this point, the study is nearly complete with stool exams completed on all 44 individuals. To date, no evidence of Strongyloides stercoralis or other intestinal parasite has been found. The IgE level results are pending and additional stools will be obtained from individuals with abnormally high values. Stools seeded with Strongyloides stercoralis and submitted to the technologist in a blind fashion have been detected, so that the techniques used are felt to be sensitive enough to pick up light infections. It would appear that the high rate of chronic Strongyloides stercoralis infections in British and Australian ex-POWs relates to their exposure on the Thai-Burma railway. This study will be concluded at this point due to negative results in sample size large enough to detect the problem if present.

LONGITUDINAL AND CROSS-SECTIONAL ECHOCARDIOGRAPHIC STUDY IN HEALTHY VOLUNTEERS

M. Wong, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Cardiology Section, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (552-52-2603)

For studying the aged heart, we postulated that subclinical heart disease is prevalent in the elderly and is detrimental to cardiac function independent of any age-related decline in cardiac performance. Thus, we proposed to evaluate the hearts of asymptomatic elderly volunteers using sensitive noninvasive methods to identify subclinical disease and to quantitate the effect on cardiac function compared to the disease-free elderly cohort.

The purpose of this prospectus is to enroll healthy volunteers in their second to sixth decades into a cross-sectional and longitudinal study of the heart. Subjects will have echocardiograms taken over a 5-year period at regular intervals and immediately following any illness and trauma. The cross-sectional data will be used as standards to interpret the cardiovascular assessments in the elderly subjects. The longitudinal data will determine the physiological variability of the echocardiographic measurement. Any additional variability demonstrated and associated with non-cardiac illness and generalized stress will be new information and will provide a basis for formulating hypotheses about aging of the heart.

THE VETERANS ALCOHOLISM SCREENING TEST (VAST) AN OUTGROWTH OF THE MICHIGAN ALCOHOLISM SCREENING TEST (MAST)

K. Magruder Habib, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Raleigh Rd., Fayetteville, North Carolina* 28301 (217-48-0825)

The Veteran's Alcoholism Screening Test (VAST), developed at the VA Medical Center in Fayetteville, N.C., is a revision of the Michigan Alcoholism Screening Test (MAST) that attempts to distinguish between past and present alcoholism. The VAST contains the original 24 questions from the MAST, but each of the 24 original MAST questions is followed by three questions designed to identify the specific time period to which an alcoholic answer to the question refers. Thus, a time frame is determined for each item on the questionnaire: within the last year, more than a year ago but not more than five years ago, and more than five years ago. Consequently, scores for the three time periods, in addition to the original MAST score, can be obtained. The weights and scoring for each of the VAST questions are the same as the corresponding MAST question. Using a sample of 118 pairs of VA ambulatory care patients and their relatives, the VAST is found to be a more valid indicator of alcoholism than the MAST based on the agreement between patient and relative scores for the current and 1-5 years time periods. This is true whether test scores are considered as integer-valued variables or converted to categorical variables.

It is also obvious that prevalence could be dramatically different using the VAST as opposed to the MAST. Looking at cumulative VAST prevalence for the current and 1-5 years time periods combined, the MAST shows a prevalence nearly twice as high.

The use of the VAST is recommended over the MAST because it is shown to be more valid, more useful, and more accurate.

RECORD REVIEW OF URINARY TRACT INFECTIONS IN SPINAL CORD INJURY PATIENTS

D.A. Evans, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *1400 Vet. of Foreign Wars Pkwy, West Roxbury, Massachusetts* 02132 (369-46-5927)

Urinary tract infections are a substantial problem for patients with spinal cord injuries despite recent advances in bladder drainage techniques which appear to have greatly reduced the occurrence of such infections. Precise data regarding present rates of urinary infection and characterization of those factors predisposing to infection are needed for any further improvement in rates of infection. The proposed study will obtain these data through a retrospective record review of admissions to the Spinal Cord Injury Unit over the past six years. Using uniform methods and objective criteria, data will be collected regarding the occurrence of urinary tract infections during hospitalization, the characteristics possibly predisposing to such infections, and those adverse outcomes possibly associated with urinary tract infections. The data will be analyzed with techniques permitting adjustment for the effects of inter-related variables. No additional personnel requirements are anticipated, and there will be no patient contact or intervention in patient care. Funds for one year is requested toward the cost of computer analyses and preparation of reports.

A STUDY OF FACTORS WHICH CONTRIBUTE TO PERSISTING PREVALENCE OF ALCOHOLISM AMONG DOMICILIARY RESIDENTS AT HAMPTON VAMC

L.M. Walker, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Nursing Service, *Kecoughtan, Hampton, Virginia* 23667 (231-42-6492)

PROJECT OBJECTIVES: Domiciliary residents will identify clusters of factors which can be associated with the persisting prevalence of alcoholism among them and which interfere with their self-care. The factors were classified as psychological, social, and cultural and related to self-image, coping ability, social interactions, and lifestyles.

PLAN: Domiciliary residents were identified through microfiched medical records and a listing of residents attending group therapy. Interviews were conducted during a two week period.

METHODOLOGY: A descriptive survey was done utilizing an interview/ questionnaire tool. The T-test was utilized to determine the level of significance of the factors.

FINDINGS: The analysis revealed ninety-one statistically significant results by the T-test. Five factors were identified as supporting the investigators's hypotheses which were: (1) inability to handle problems, (2) inability to accept suitable means of relaxation, (3) inappropriate attitudes toward the use of alcohol, (4) manner in which they consume alcohol, and (5) interference with adequate food intake. There were twelve non-supporting factors which were: (1) dissatisfaction with self, (2) lack of self-confidence, (3) inability to control emotions, (4) feeling of inferiority, (5) feeling of guilt, (6) over-dependency, (7) inadequate relationships with others, (8) inability to accept advice and/or suggestions from others, (9) intake of alcohol as part of their daily activities, (10) familial problems resulting from their alcohol intake, (11) preoccupation with alcohol and drinking, and (12) use of tranquilizers. Residents suggested what helped them stay sober as responses to the open-ended questions. These responses were positively related to the supporting factors. The responses were the basis for the interventions recommended.

HEMATOPOIETIC EFFECTS OF CIMETIDINE

J.H. Saiers, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Hematology Oncology Section, *2100 Ridgecrest Dr. S.E., Albuquerque, New Mexico* 87108 (585-20-0188)

PROJECT OBJECTIVES: Objectives to determine the incidence and etiology of hematopoietic toxicity from the drug Cimetidine.

PLAN: Cimetidine is a commonly used H2 histamine receptor. We plan to look at patients in the General Medicine and GI clinics who are on Cimetidine. We will obtain routine CBC, Platelet counts and Diff. counts from the patients on Cimetidine in these clinics. Length of time and dose of Cimetidine will be recorded. Any patients found to have a cytopenia will undergo bone marrow examination to try to determine etiology of this drug.

CLINICAL RELATIONSHIP: Since this drug is a commonly used agent and some patients have been reported to have hematologic toxicity from the drug, it is important to look at the incidence as well as try to determine etiology of this toxicity.

CASE CONTROL STUDY OF LUNG CANCER IN FORMER MALE RESIDENTS OF CUBA

M.B. Troner, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *1201 Northwest 16th St., Miami, Florida* 33125 (054-34-0287)

The Health Systems Division of Equifax is conducting a two year epidemiologic study on the health effects of different smoking habits. This study is being conducted under subcontract to Enviro Control, Inc. of Rockville, MD, for the Smoking and Health Program funded by the National Cancer Institute. Incident cases of lung cancer in Cuban males in the Miami/Dade County area will be identified and interviewed. Each case will be assigned an age matched (plus or minus 5 years) hospital and a neighborhood control.

Newly diagnosed cases of lung cancer will be identified through the pathology departments of participating hospitals. The physician of record will be contacted to determine the patients eligibility as a Cuban and to obtain consent to interview the patient. Hospital controls will be identified through records of hospital admissions and the same procedures for contacting attending physicians will be followed. Neighborhood controls will be located from a predetermined search pattern based on the address of a lung cancer case.

After signing a consent form, each subject will be interviewed about his work history, personal habits such as smoking, family medical history and diet. All cases and controls will be interviewed in the same manner by trained interviewers. The interviewers will not be aware of a subjects diagnosis or control status and all responses are held in confidence.

HISTOCOMPATIBILITY, VIRAL AND IMMUNOGENETIC FACTORS IN ALCOHOLIC AND NON-ALCOHOLIC CIRRHOSIS OF THE LIVER

N. Ravendhran, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *1201 Northwest 16th St., Miami, Florida* 33125 (213-82-2599)

The specific aims of the proposed study are threefold: first, to determine the frequency of the histocompatibility antigenic types in alcoholic, post-hepatitic, and cryptogenic cirrhosis: second, to determine the incidence of serological parameters of type A, type B, and non-A, non-B, hepatitis viruses among patients with alcoholic and non-alcoholic cirrhosis; and finally, to characterize the binding of immunoglobulin to hepatocytes in liver biopsy specimens from patients with alcoholic and non-alcoholic cirrhosis. This study will be carried out in patients with chronic liver disease who have been admitted to the hospital for diagnosis and/or management of their liver disease and who would normally require a liver biopsy for proper management of their disorder. Demographic and pertinent historical data as it relates to chronic alcoholism and the epidemiology of viral hepatitis will be abstracted from the patient's medical records. Tissue typing, hepatoglobin phenotypes, serological assays for the hepatitis viruses, autoimmune antibody determinations and standard liver chemistries, including serum bile salt analyses will be performed on blood specimens. In addition to the standard processing of the liver biopsy specimen for light microscopy, immunofluorescent studies will be performed to characterize the nature of immunoglobulin binding to hepatocytes.

The results of these studies should better elucidate the importance of genetic predisposition, viral hepatitis, and immunoglobulin binding in the pathogenesis of cirrhosis of the liver.

ATHEROSCLEROSIS IN UREMIA

D. Sherrard, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *4435 Beacon Ave. S., Seattle, Washington* 98108 (538-30-5484)

OBJECTIVE: To clarify the causes and significance of the accelerated atherosclerosis in patients with chronic renal failure.

RESEARCH and METHODOLOGY: We have evaluated this with prospective epidemiologic assessment of known risk factors and clinical-biochemical studies characterizing the lipid disorder.

FINDINGS: Our work has documented that cardiovascular disease is consequence, at least in part, of high blood pressure, smoking and elevated triglyceride levels. We have also shown that the elevated triglyceride levels can be a consequence of a variety of disturbances in uremia that inhibit lipo-protein lipase. We have also shown that clofibrate can be used safely, at very low doses, to lower triglyceride levels in these patients.

The most recent findings suggest an interaction of drugs, such as androgens, B blockers and cimetidine, and abnormal calcium metabolism with the lipid disorder. Work in progress is attempting to clarify this interaction.

3.1437,

THE SPREAD OF HEPATITIS B FROM HEALTH CARE DELIVERERS

L.I. Lutwick, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *Hwy. 6 W., Iowa City, Iowa* 52240 (067-38-3575)

It has been estimated that as many as 1 percent of health care professionals are healthy carriers of the hepatitis B virus. These individuals represent a considerable problem in health care delivery due to the potential for transmission of the virus to the patient population they care for. This risk of transmission is felt to be small but is, as yet, essentially undefined. The objective of this proposal is to better define the risks of transmission of hepatitis B virus by health care deliverers to patients in a prospective manner. The results will be helpful to minimize transmission to the patient by identifying certain carrier groups that seem to be associated with infectivity. In addition, by providing data on infectivity, the study will prevent future unilateral, unfounded decisions by health care agencies to prohibit such carriers from participation in primary health care delivery.

THE EFFECT OF LIFE EVENTS ON ALCOHOLISM

A.P. Schless, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *38th & Woodland Aves., Philadelphia, Pennsylvania* 19104 (199-28-4236)

The Effect of Life Events on Alcoholism research project has screened one hundred and ninety-three patients for eligibility to date. Out of this, fifty patients did not meet criteria and forty subjects and co-informants have been entered into the study. The remainder of the patients have either dropped out of the program, still considering participation or arranging an interview date. The major difficulty has been the lack of a willing co-informant. Methods to overcome these difficulties are being considered.

An addendum to this study has been approved in which a co-informant is not necessary. A review of research presently available on life events and alcoholism has been completed and will be submitted for publication.

NHLBI TWIN STUDY FOLLOW-UP EXAMINATION

T. Makinodan, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Geriatric Research Education & Clinical Center, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (575-22-9038)

The overall objective of NHLBI Twin Study is to examine familial aggregation of risk factors for coronary heart disease (CHD) in the attempt to separate environmental from genetic contributions in middle-aged white, male monozygotic and dizygotic twins. The first task is to repeat the core examination performed in this group 10 years ago consisting of a history, physical examination and laboratory assessment oriented toward CHD and its risk factors. The second task consists of ancillary proposals in immunology, cardiology, pulmonary and psychology.

The initiation of the examination of the twins has been postponed to January, 1981, by NHLBI due to administration delays. Planning and organizing at Wadsworth has been completed.

CONSIDERATIONS ON THE PATHOLOGY OF THE THYROID GLAND IN BRAZIL (ANALYTIC STUDY OF 3771 PATIENTS)

J.B. Botelho, Universidade do Amazonas, *Av. Eduardo Ribeiro, 520 sala 705, Manaus 69000, Amazonas, Brazil* (108)

OBJECTIVE: In the Amazon region there is a high incidence of iodine-deficiency goiter. National and international statistics show more thyroid cancer in areas with a high incidence of goiter. Once the data have been processed by computer it will be possible to prepare a document indicating the necessity of modifying or changing the eating habits of this population. This should result in medium and long term change in the incidence of goiter/thyroid cancer in the Amazon region.

APPROACH: This is an analytical study of 3771 patients with disease of the thyroid gland, divided into two groups: surgical and clinical. Data obtained from the patients' records during 45 years (1930-1975) of the Thyroid Surgery Service will be analyzed by the Data Processing Service of the Universidade dos Amazonas and will permit the preparation of reports on the entire body of patients and the establishment of relative incidence, frequency, treatment and cure of patients. BRAIN INJURIES AND PROTECTIVE SPORTS EQUIPMENT

E.A. Ripperger, University of Texas, Austin Campus, School of Engineering, Dept. of Aerospace Engineering & Engineering Mechanics, *200 W. 21st, Austin, Texas* 78712

DESCRIPTION: This is a continuing study of the basic mechanics of head injuries, based on the premise that the neurosurgeon diagnosing and treating head injuries is in a better position to make his diagnosis and to determine the treatment needed if he knows the mechanism by which the injury was produced and the area of the brain most likely to be affected.

These studies have now been broadened to include the evaluation of protective sports equipment, with particular emphasis on protective helmets. The National Operating Committee on Standards for Athletic Equipment (NOCSAE) has issued a set of specifications for football helmets, and the NCAA now requires that helmets which meet these specifications be used in games played under the jurisdiction of NCAA.

Unfortunately, the acceptance or rejection criteria in the NOCSAE specifications are based on data published several years ago. These data are given in the form of a curve of acceleration versus duration of acceleration. The curve is known in the industry as the Wayne State University Tolerance Curve. Most authorities probably agree that this curve leaves something to be desired as an injury criterion. Nevertheless, since it seems to be the best that is available, it is used. The standard testing procedure based on the WSU Tolerance Curve provides essentially a go - no go decision with little indication of the comparative performances of different helmets. The objectives of this research are to develop procedures for making comparative evaluations and to correlate these evaluations with injuries actually observed on the football field and elsewhere. It should be possible, in time, to determine what conditions produce concussion, and how helmet construction affects those conditions.

Measurements of head accelerations produced by the impact of a projectile on a headform protected by a helmet are being made in the laboratory, and a mathematical model of the system is being developed.

Our preliminary test results indicate that there are noticeable differences in helmet performance, and there is some correlation between the make of the helmet and the incidence of head injuries.

PESTICIDE MONITORING

J.C. Street, Utah Higher Education System, Utah State University, Agricultural Experiment Station, Dept. of Animal Dairy & Veterinary Sciences, *Main Bldg., Room 104, Logan, Utah* 84321 (0078933)

OBJECTIVE: Assist the Human Effects Monitoring Branch, Office of Pesticide Programs, U.S. Environmental Protection agency, in determining the magnitude of human exposure to pesticides, providing expert consultant service to review, analyse, and validate pesticide risk and benefit data, conducting epidemiologic studies of various exposed population groups, devised means of recohnition and diagnosisof pesticide effects in man.

APPROACH: Maintaining an inventory of pesticide usage in the study area (Utah) and use patterns; make human blood, milk or other tissue analyses in collaboration with the national monitoring program; establishing a group of certified consultants and coordinating their data review; development of methods suitable for population and environmental monitoring; developing special studiesof pesticides health effects; and participation in Pesticide Incident investigations as needed in the study area and elsewhere on request of the OPP.

QUANTITATIVE AND QUALITATIVE CORRELATION BETWEEN INCIDENCE OF MORTALITY AND MORBIDITY IN THE DOUBS AREA

S. Schraub, Centre Pierre Masson, *Pl. St. Jacques, c/o Centre Hospitalo Univer., 25030 Besancon, France*

OBJECTIVE: Quantitative and qualitative correlation of the incidence of mortality with the incidence of morbidity in a defined area.

APPROACH: Quantitative correlation of the incidence of morbidity with the incidence of mortality is possible with data from INSERM (National Institute of Medical Research), which officially collects mortality data based on death certificates, and with data from the Population Cancer Registry of Doubs. These correlations are useful in testing the validity of the cancer registry and they also enable proper appreciation of the differences between incidences of mortality and morbidity which appear not to be correlated with the the survival of patients with cancer of some specific sites. Qualitative correlation gives some data about the validity of death certificates in France.

PROGRESS: Seventeen percent of the data found in death certificates are incorrect due to imprecisions (2.5%) and errors (14.5%). Data on leukemia, cancer of the uterus and hepatic cancer contain most errors.

DETECTION OF STAPHYLOCOCCAL ENTEROTOXIN IN FOODS

M.S. Bergdoll, University of Wisconsin, Madison Campus, Food Research Inst., *Madison, Wisconsin* 53706 (0055581)

OBJECTIVE: Evaluation and improvement of methods for the detection of staphylococcal enterotoxins in foods; Preparation of specific antisera and their homologous enterotoxins for use in performing tests for enterotoxins.

APPROACH: Published methods for enterotoxin detection will be tried with various foods to determine which is most suitable for routine laboratory use. Efforts will be made to simplify and shorten the procedures where possible. Purified enterotoxins will be used as antigens to prepare specific antisera, which will be standardized and made available for enterotoxin detection tests in other laboratories. These reagents are not available commercially and their preparation will require additional research, particularly with the newer types D and E.

PROGRESS: The objectives of this project are to determine the best methods available for detection of enterotoxin in foods and develop new ones if possible, train people in the use of the recommended methods, and supply food industry laboratories with reagents for enterotoxin detection. The Food Research Institute procedure of Reiser, Conaway and Bergdoll (Appl. Microbiol. 27:83, 1974) is still the method of choice and is the one we train people to use. Several people went throught our training course this year. We have developed a radioimmunoassay (RIA) procedure (Appl. Environ, Microbiol. 36:421, 1978) which we think is the best method for detecting enterotoxin in foods. Not all laboratories can use it because of the need for special equipment and the purified enterotoxins. We have been able to detect enterotoxin in foods which were involved in food poisoning outbreaks with this method when we could not find it with the other method. We found enterotoxin (SEA) in pre-cooked batter dipped cod, the cause of a food poisoning outbreak in South Dakota and, also, in ham from a food poisoning outbreak in Wisconsin. We examined 30 cans of Lobster Bisque which had been implicated in an outbreak in 1975 and found one can to contain very small amounts of SEA (20 ng/100 ml). This casts some doubt on the Lobster Bisque as the cause of the food poisoning. Enterotoxin reagents were supplied to several food companies.

3.1446,

WILDLIFE RESERVOIRS OF ARBOVIRUSES

T.M. Yuill, University of Wisconsin, Madison Campus, Agricultural Experiment Station, Dept. of Veterinary Science, *116 Agricultural Hall, Madison, Wisconsin* 53706 (0003021)

OBJECTIVE: Determine the occurrence and epidemiological significance of LaCrosse virus variants, and the relationship of these variants to mosquito vectors and wildlife hosts.

APPROACH: LaCrosse viruses will be isolated from wildlife hosts and mosquito vectors inn SW Wisconsin. These isolates will be tested to determine if plaque, mouse virulent (or attenuated), temperature sensitive, thermal stable or antigenic variants occur. These variants will be tested for their ability to infect wildlife hosts and to be transmitted by Aedes triseriatus, the natural vector.

PROGRESS: The role of medium-sized forest mammals in LaCrosse (LAC) virus epidemiology is being evaluated. LAC virus-infected mosquitos Aedes triseriatus infected red foxes. The foxes became infected and developed a viremia of 4-5 days duration and of sufficient amplitude to infect susceptible mosquitos which, in turn, transmitted the virus to susceptible chipmunks, a common forest host of this virus. Thus it appears that the red fox can potentially serve as a reservoir and dessiminator of LAC virus. Sentinel foxes placed in an endemic area became infected, indicating that transmission to foxes does occur commonly in nature. Experiments with captive raccoons revealed no viremia and it appears unlikely that they play a role as LAC virus reservoirs. It was shown that the snowshoe hare is capable of developing a significant viremia following experimental infection with Powassan (POW) virus. However, within the boreal forest in Northeastern Alberta, infection of snowshoe hares by POW virus was relatively uncommon during the period of our study. Our field studies did indicate that deer mice in this area were commonly infected with Modoc (MOD) virus. This virus also infects humans and we have evidence of antibiodies in local Indian population in the area. Ecological changes associated with mining of the Alberta tarsands appeared to increase deer mouse populations and the potential risk for increase of Modoc virus transmission in the area.

A LONG-TERM FOLLOW-UP STUDY OF WOMEN USING DIFFERENT METHODS OF CONTRACEPTION

M.P. Vessey, University of Oxford, Dept. of Social & Community Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom*

Seventeen family planning clinics are participating in a prospective study of the beneficial and adverse effects of different methods of contraception. The investigation is funded by the Medical Research Council. Over 17,000 women are under observation; on admission to the study 57% of them were using oral contraceptives, 25% were using a diaphragm and 18% were using an intrauterine device. During follow-up, each subject is questioned at return visits to the clinic, and a record of pregnancies and their outcome, hospital visits, changes in contraceptive methods and the results of cervical smears is accumulated. Women who default are sent a postal questionnaire and if this is not returned, they are telephoned or visited in their homes and the necessary information is collected. So far, data representing 90,000 woman-years of follow-up are available for analysis. Losses to follow-up have been fewer than 1 per 100 per annum and adherence to the method of contraception in use at entry has been reasonably good. Analyses completed to date concern the entry characteristics of the subjects, patterns of morbidity, outcome of pregnancy, fertility after discontinuation of contraception, and efficacy of different methods. Most of the findings fit in well with those of retrospective studies and with those of the Royal College of General Practitioners prospective study. A detailed interim report of the study was published in the Journal of Biosocial Science in October 1976. The study continues.

CASE-CONTROL STUDY OF THE POSSIBLE RELATIONSHIP BETWEEN ORAL CONTRACEPTIVES AND CANCERS OF THE BREAST, ENDOMETRIUM AND OVARY

M.P. Vessey, University of Oxford, Dept. of Social & Community Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom*

Although a great deal is known about the short- and medium-term hazards of oral contraceptives, there is still a great need to monitor possible carcinogenic effects. In this investigation, women of childbearing age newly presenting with cancers of the reproductive system at any of six London teaching hospitals are interviewed, together with matched controls. The study has been in progress for about eight years and now includes nearly 1,000 cases of cancer of the breast. Results concerning the first 90 cases of breast cancer were published in the British Medical Journal in September 1972, the next 232 cases in the Lancet in April 1975, and the next 385 cases in the British Medical Journal in July 1979.

THE DETERMINATION OF HIGH RISK GROUPS FOR BREAST CANCER SCREENING

B.A. Thomas, Midhurst Medical Research Inst., *Midhurst, Sussex, United Kingdom*

Women aged 35 and over who have a family history of breast cancer and/or have had no viable pregnancy before that age, and/or have had a previous breast biopsy or cyst aspiration and/or in whom clinical examination is equivocal or difficult in view of nodular breasts are being screened by clinical examination with emphasis on minimal signs and mammography. Women with a clinical abnormality have the standard lateral and cephalocaudal mammographic views; the 'normal' women have single view only with breast compressed in a plane from the axilla to the xiphisternum giving a 45 degree oblique view with excellent visualization of the breast and a radiation exposure of around 0-18 rad. Detection rates are being compared with those from the screening of a similar group of women in Guildford, but using standard mammographic views for all women. To date the cancer rate in asymptomatic women is the same in the two groups. Epidemiological, clinical and mammographic risk factors are being studied.

STUDY OF CANCER OF THE LUNG AND STOMACH, AND OF BRONCHITIS MORTALITY IN RELATION TO URBAN FACTORS

R.E. Waller, Medical Research Council, *20 Park Crescent, London W1N 4AL, England, United Kingdom*

This is a study based on published mortality data. One of the features of the distribution of lung cancer deaths in recent decades has been the relatively high rate in urban areas, but the pattern is changing gradually and the death rates currently experienced by recent cohorts are not much higher in urban than in rural areas, a change most marked in London. These findings are being considered in relation to the substantial changes in pollution by smoke, as well as changes in smoking habits, and possible biases introduced by selective migration. The data have been accumulated gradually, as they become available, starting with deaths in 1951, and the object is to assess the trends over a 25 year period, arranged on a cohort basis. Data from this study for the Greater London area are also being used in connection with an investigation of lung cancer incidence among London Transport workers, over a similar 25 year period. The experience of the London Transport group as a whole is being compared with that of the general population, and incidence rates are being calculated for several job categories with a view to exploring the effects of exposure to diesel fumes.

LONG-TERM FOLLOW-UP OF CHILDHOOD CANCER SURVIVORS

G.J. Draper, University of Oxford, Dept. of the Regius Professor of Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom*

There is considerable concern about possible long-term effects of radiotherapy and chemotherapy used in treating children with cancer, including the induction of second primary tumors. It has also been suggested, though at present direct evidence is lacking, that improvements in survival for certain categories of tumor, and the subsequent increase in the number of children born to survivors, will lead to the recognition that there is a genetic component in the aetiology of some of the cancers of childhood comparable to that for retinoblastoma. The Childhood Cancer Research Group is coordinating a collaborative study which will eventually include records of about 6,000 children who have been treated for cancer and survived for at least three years. These survivors will be followed up to determine the incidence of second tumors and also the incidence of abortions, stillbirths, congenital defects and malignant disease among their children. For children treated in Scotland, subsequent hospital admissions, school health records and other medical records are being studied and compared with corresponding records for a sample of controls, using record linkage. Various other long-term effects may be studied for cases from particular centres. It is planned also: (1) To carry out laboratory studies including hematological studies, cytogenetics and possibly measurement of immunoglobulins for some of the cases included in the study and (2) to establish a pathology registry for children in whom second primary tumors occur.

CHILDHOOD CANCER REGISTRY

G.J. Draper, University of Oxford, Dept. of the Regius Professor of Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom*

A registry for childhood neoplasms occurring in England, Scotland and Wales has been established with the following objectives: (1) To obtain estimates of incidence, mortality and survival rates, (2) to provide a basis for epidemiological, genetic and medical care studies, (3) to provide a service to other research workers. Registrations of cancer in children below age 15 and deaths below age 16 are reported to the Childhood Cancer Research Group by the Office of Population Censuses and Surveys, the Information Services Division of the Scottish Health Service, regional cancer registries, and clinicians. This is supplemented by clinical information derived from hospitals and general practitioner records. A classification

system particularly appropriate for childhood cancer and based on the International Classification of Diseases for Oncology has been developed. Comprehensive data on incidence, mortality and survival have been analyzed and will be published by the Office of Population Censuses and Surveys. Studies currently in progress include: (1) Comparisons of survival rates for children with leukemia and Wilms' tumor included in MRC clinical trials with those for children not included, (2) the provision of treatment for children with cancer, (3) studies to determine whether there is an increased incidence of cancer in the parents of children with cancer.

PROLONGED AND VARIABLE EXPOSURE TO ASBESTOS FIBER

J.C. Cochrane, South African Dept. of Health Welfare & Pensions, National Centre for Occupational Health, Dept. of Occupational Medicine, *P.O. Box 4788, Johannesburg 2000, South Africa*

Ninety-two senior staff members of a large asbestos/cement company with factories spread over the country are being studied. This company manufactures asbestos/cement products, roof and ceiling sheets, insulation boards, piping and moulded goods and the staff have been exposed to all of these as well as to visits to asbestos mines. Exposure has been estimated as heavy in 17, moderate in 23 and light in 52 persons. Medical examination, including X-ray, carried out in 1973, 1974 and 1976 revealed pleural thickening in 43 and thickening with parenchymal change in 3 persons. Follow-up of the cohort continues.

CANCER REGISTRATION IN EAST AND CENTRAL AFRICA

P.J. Cook, University of Oxford, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom*

Data has been collected by regular postal questionnaire to rural hospitals in Uganda, Kenya, Tanzania, Malawi and Zambia, and by establishing a cancer registrar in the major hospitals of Nairobi, Dar es Salaam, Blantyre, Lusaka and Kitwe. The data is in the final stages of analysis; incidence rates have been calculated for the towns and proportional frequencies for the rural areas; comparisons are being made between the patterns of variation for individual cancers and environmental and sociological variables.

POSSIBLE CARCINOGENIC HAZARDS OF HAIR DYE USAGE

I.K. Crombie, Regional Cancer Registry, *c/o Queen Elizabeth Med. Ctr., Birminghan B15 2TH, England, United Kingdom*

The present project is a feasibility study to determine whether a larger scale investigation could usefully be undertaken. One source of data is by questionnaire to volunteers to record their pattern of usage and to form an index file for linkage with health and mortality records. The second source is from hairdressers and others whose work brings them frequently into contact with hair dyes. Again, their health and mortality records will be related to extent of exposure.

SHORT-TERM VARIATION IN PRE-NATAL CANCER RISK

J.F. Bithell, University of Oxford, Dept. of Biomathematics, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom*

An analysis has been undertaken in which all deaths from malignant disease of British children between 1953 and 1971 have been tabulated by month of birth and age at death. Comparative 'expected' numbers have been computed with allowance for survey coverage, cohort size and secular trends. A program has been developed which is designed to correlate these series of observed and expected numbers in an appropriate manner with any time-varying factor of interest. A study of the temporal association with influenza and poliomyelitis incidence has been completed; the data are available for the analysis of any monthly observations that may be of etiological interest or significance.

CANCER MORTALITY IN 11,121 MALES BORN 1903-1928 - A COMPONENT OF A YUGOSLAVIAN CARDIOVASCULAR DISEASE STUDY (ABBREV)

D. Kozarevic, Inst. of Chronic Diseases & Gerontology, Dept. of Chronic Diseases, *Slobodana Penezica 35/2, Belgrade, Yugoslavia*

The Yugoslavia Cardiovascular Disease (CD) study was initiated in 1961-1963 in two geographical areas in Yugoslavia (Tuzla and Remetinec). The study population comprised 11,121 males, both urban and rural residents, aged 35-64 at the initial examination in 1964. This population was subsequently re-examined by the same study teams on two occasions, the last time seven years following the initial examination. The methodology and results were compared with those of the Framingham Study, USA (J. Chron. Dis., 29:405-411, 1976 and Am. J. Epidem., 104, 133-140, 1976). Mortality follow-up for the cohort is essentially complete. The centralized mortality register makes it possible, in principle, to identify the death of any specific person occurring within the country. The re-examination of the cohort provided means to check the completeness of this mortality follow-up and update the mortality lists. There is a distinct excess of cancer mortality in the Yugoslavian study population, the age-adjusted rate being 60% higher than in Framingham. The most striking excess is for stomach cancer which accounts for a vastly greater proportion of cancer deaths in Yugoslavia (23.2%) than in Framingham (3.7%). As in other populations, this excess appears to be accompanied by a lower mortality from cancer of the large intestine. If the age-adjusted mortality for cancer is expressed as a percentage of the total age-adjusted mortality, Framingham and United States mortality are very similar whereas cancer mortality in the Yugoslavian study areas is higher than in the country as a whole. There is a strong likelihood that the Yugoslavian CVD study areas have higher than the average cancer mortality for the country. These findings are being further investigated.

NON-HODGKIN'S LYMPHOMAS IN CHILDREN

L.I. Schwartz, Hospital de Ninos de Buenos Aires, Dept. of Pathology, *Gallo 1330, 1425 Buenos Aires, Capital Fed, Argentina*

From 1965 to 1977 a total of 140 children with non-Hodgkin's lymphomas attended the Oncology Unit of the Children's Hospital of Buenos Aires. A male preponderance was found and the peak age was five years. The most frequent location was the abdomen, in particular the ileocaecal region. The histological pattern in a high percentage was the diffuse poorly differentiated lymphocytic form. The main objectives of future epidemiological research will be: detection of primary immunodeficiency disorders, and evaluation of the frequency of herpes and/or other virus infections.

EPIDEMIOLOGICAL STUDY OF CANCER IN ALGERIA 1946-1955 AND 1966-1975

A. Yaker, Centre Hospitalo Universitaire Mustapha, Laboratoire Central dAnatomie Pathologique et de Cytologie, *Algiers, Algeria*

Data on histologically diagnosed cases of cancer are collected from pathology laboratories in Algiers, Oran and Constantine which cover the whole country. This includes: histopathological diagnosis; site; age; sex; ethnic group and geographical distribution. The relative frequency will be studied for two ten-year periods. If feasible, minimum incidence rates will be calculated and high risk groups determined as part of planning for a national program of cancer control.

INCIDENCE OF CANCER IN WESTERN AUSTRALIA

M.M. Lugg, University of Western Australia, Dept. of Health & Medical Services, *Perth, W. Australia 6009, Australia*

Western Australia has a diverse climate over its 1,000,000 square miles of area, and a scattered population of approximately 1,000,000. This population has remained relatively stable, making possible extensive epidemiological analysis, including long term follow-up. Cancer incidence, by site, age, sex, geographic location of patient, work history, and detailed treatment for three months following diagnosis is currently being analyzed.

CARCINOMAS OF THE URINARY TRACT AND ASSOCIATION WITH ANALGESIC ABUSE

G. Duggin, Royal Prince Alfred Hospital, Renal Unit, *Missenden Rd., Camperdown, Sydney, N.S.W. 2050, Australia*

The aim of the study is to determine the incidence of carcinomas of the urinary tract in patients who abuse analgesics, particularly those containing aspirin, phenacetin, caffeine, paracetamol and salicylamide. Patients studied will be those referred to Royal Prince Alfred Hospital with analgesic-induced renal disease (analgesic nephropathy) or those patients known to abuse analgesics. This group of patients will be followed prospectively to determine the frequency and type of carcinomas of the urinary tract and which analgesic is specifically associated with the development of these carcinomas. It is anticipated that between 50 and 400 such persons will be followed. Controls will be age- and sex-matched patients with comparable renal disease, who do not consume analgesics, attending the same clinic.

DYSPLASIA OF THE UTERINE CERVIX AND CANCER RISK

V.F. Oliveira, Brazilian Research Inst., Dept. of Gynaecological Cancer Prevention, *Rua Florida 295 Vila Barcelona, Sao Caetano do Sul, Sao Paulo, Brazil*

The aim is to study cancer risk in patients with dysplasia of the uterine cervix using biopsy examination. Three hundred ninety-seven patients in whom colposcopy revealed atypical aspects - mosaic, punctation, leukoplasic or atypical vessels - were examined after three months, then every semester for two years, then yearly until completion of the research which covered the seven year period from 1972-1979. Of the 210 patients with slight dysplasia, 7 showed carcinoma in the subsequent examination (3.32%); of the 35 patients with moderate dysplasia and under 30 years of age, three presented carcinoma in the examinations that followed (8.57%); of the 84 patients with moderate dysplasia and over 30 years old, 13 presented carcinoma in the examination that followed (15.47%); of the 68 patients with acute dysplasia, 16 presented carcinoma in the examination that followed. Follow-up continues.

THYROID CANCER AND ENDEMIC GOITER

G. Riccabona, Leopold Franzens Universitat Innsbruck, Universitaetsklinik, *Anichstr. 35, 2 6 Universitatsstrasse, A6020 Innsbruck, Austria*

For decades a possible correlation between endemic goiter and thyroid cancer has been discussed. So far only contradictory evidence has been obtained, perhaps due to the fact that epidemiological data from endemic goiter areas in developing countries are insufficient. The present study includes epidemiological data from western Austria (about 90 percent of thyroid cancer cases from this area seen in this department) where extensive studies on the incidence of endemic goiter have also been carried out. These figures will be compared with relevant data from other countries all over the world.

KIDNEY CANCER AND TOBACCO CONSUMPTION

C. Vutuc, Universitat Wien, Inst. of Hygiene Social Medicine & Epidemiology, Arbeitsgruppe fuer Sozialmedizin und Epidemiologie, *Kinderspitalgasse 15, 1095 Vienna, Austria*

The aim of this retrospective survey is to determine if smoking causes kidney cancer. The emphasis will be on cancers of the renal pelvis - about 150 such cases will be studied - although cancers of the renal parenchyma will also be included. For each case two matched controls with non-tobacco selected disease will be interviewed. The results of tobacco smoking in both cases and controls will be compared with data from the Austrian population collected in 1972 and 1977.

3.1472,

INCIDENCE OF BREAST CANCER IN CANADIAN INDIANS AND ESKIMOS CORRELATED WITH THEIR CHANGING LIFE-STYLES

M.S. Beare, Canadian Dept. of National Health & Welfare, Medical Services Branch, *401 Toronto Dominion Tower, Edmonton Centre, Edmonton, Alberta, Canada*

Cancer of the breast was considered to be unknown in Canadian Indians and Eskimos 25 years ago. It is still rare in Eskimos but is fairly common in Indians, though probably less common than in the general Canadian population. The question of whether there has been a real change in incidence is being studied, and, if so, whether the change is associated with the marked changes in life-style of the native people in recent years. Of particular interest is whether prolonged breast feeding (of about two years) can be shown to have protected women from breast cancer. Diet is also being examined.

GEOGRAPHICAL DISTRIBUTION OF MALIGNANT NEOPLASMS OF THE BRAIN IN CANADA

I.C. Neutel, University of Ottawa, Faculty of Medicine, Dept. of Epidemiology & Community Medicine, *1145 Carling Ave., Lady Grey Bldg., Ottawa, Ontario, Canada* K1Z 7K4

Malignant neoplasms of the brain have received very little epidemiological attention in spite of the low survival rate and their occurrence in childhood or early adulthood. A few studies dealt with their general distribution in the United States and Denmark and only one studied the geographical distribution in relation to environmental factors. This project will study the geographical distribution of brain tumours across Canada using both mortality and incidence data by calculating age-adjusted mortality and incidence rates for census divisions. These rates can be related to various environmental variables known for the census divisions. In addition, this study will investigate the occupations recorded for a selected group of brain tumour deaths and compare them with those of a matched group of controls. Of special interest will be occupations likely to involve chemical or radiation exposure. Prenatal radiation has been shown to increase the risk of childhood cancer of the central nervous system, and the same situation may apply to adult brain cancer.

URBAN MORTALITY STUDY

D.T. Wigle, Canadian Dept. of National Health & Welfare, Lab. Centre for Disease Control, *Tunneys Pasture, Ottawa, Ontario, Canada* K1A 0L2

Death certificates for all deaths during 1971 among residents of the 21 largest census metropolitan areas in Canada have been searched to identify the census tract of residence (census tracts are small statistical areas established in large urban communities, usually have populations between 2,500 and 8,000, are relatively uniform socio-economically, have permanent boundaries and are as compact as possible). Death rates by sex, age and cancer site will be calculated for census tracts aggregated according to median household income. Correlations between mortality rates and census tract characteristics will be sought.

THE ROLE OF EXOGENOUS ESTROGEN IN NEOPLASIA AND HYPERPLASIA OF THE ENDOMETRIUM

C.A. Woolever, McMaster University, School of Medicine, Dept. of Obstetrics & Gynecology, *1200 Main St. W., Hamilton, Ontario, Canada* L8S 4J9

The objective is to assess the significance of exogenous estrogen use in the development of endometrial carcinoma and hyperplasia. Newly diagnosed endometrial carcinomas and hyperplasias were obtained from 21 metropolitan hospitals in Toronto. From April 1, 1977 to March 31, 1978, 144 carcinomas and 575 hyperplasias were diagnosed among metropolitan residents. Tissue slides for both case groups were reviewed independently by two senior pathologists. For each of the confirmed carcinoma and hyperplasia cases, two age-matched neighborhood controls were used. Both cases and controls were interviewed in their homes. Detailed information was sought on medications, gynecological histories, episodes of bleeding and associated surgical procedures. The degree of medical surveillance is being assessed in addition to other confounding variables. Interview information is being verified against available medical records from hospitals and physicians' offices. The analysis is expected to be completed by June 1980.

CASE-CONTROL STUDY OF ETIOLOGICAL FACTORS IN HEAD AND NECK CANCER

J.M. Elwood, Cancer Control Agency of British Columbia, Epidemiology Division, *2656 Heather St., Vancouver, British Columbia, Canada* V5Z 3J3

The objective of the study is to evaluate the association of alcohol, tobacco and occupation to cancer of the head and neck, and to determine whether such exposures are independent or interactive. It is planned to interview all new patients with these tumors seen at the Cancer Control Agency of British Columbia (which includes about 90 percent of new cases in the province) over a 3 1/2 year period, to give a total of about 350 cases. The control group will consist of an age-and sex-matched group of patients with other tumors chosen on the basis of lack of association with the main exposures, for example breast and gynecological cancer in women, chronic lymphomas and multiple myeloma, and prostatic tumors in men. The interview will provide information on a lifetime occupational history and quantification of current and past tobacco and alcohol usage habits.

MALIGNANT LYMPHOMA IN COLOMBIA IN RELATION TO EPSTEIN-BARR VIRUS

A. Duenas Lehmann, Universidad del Valle, Dept. of Microbiology, *Apartado Aereo 2188, Cali, Colombia*

The objective of this study is to explore the role of Epstein-Barr virus (EBV) in Hodgkin's disease and other malignant lymphomas in Colombia. Serum samples are obtained from patients and appropriate controls, and malignant lymph nodes from biopsy or autopsy. The samples are immediately frozen and stored in low temperatures for periodic shipments to laboratories in the United States for detection of viral markers in both serum and tissues. There is as yet no indication of an association between EBV infection and malignant lymphoma in Colombia, but at least 50 cases will have to be examined before any conclusion can be drawn.

MALIGNANT POTENTIAL OF ORAL LICHEN PLANUS

P. Holmstrup, Rigshospitalet, Dept. of Oral Medicine & Oral Surgery, *Juliane Mariesvej 16, DK2100 Copenhagen, Denmark* (01105)

The objective of this study is to obtain information on the potential for malignant transformation of oral lichen planus lesions over a 15-year period. Seven hundred (700) patients with histologically verified oral lichen planus are being followed. The patients are asked about past and present oral symptoms and smoking habits. The location and type of oral lichen planus lesions are registered and photographed. After the first examination the patients are seen once a year, except those with epithelial dysplasias who are seen every three months. At the follow-up examinations all changes in the lesions are recorded, photographed and, if necessary, biopsied. So far, five patients have been found with a simultaneous occurrence of lichen planus and erythroplakia. The influence of smoking on the lesions will be studied.

CANCER OF STOMACH AND RECTUM IN EGYPT AND SOME OTHER ARAB COUNTRIES

Y.Z. Mohran, Ain Shams University, Faculty of Medicine, Gastroenterology Unit, *Abbassia St., Cairo, Egypt*

Cancers of the stomach and rectum, common in other parts of the world, seems to be rather uncommon in Egypt and other Arab countries, an observation based on hospital statistics. A surprisingly high frequency of rectal cancer in younger age groups has already been uncovered which seems unrelated to previous parasitic infection, dietary or immunological factors. In Ein Shams University and Kings Hospital in Medina, located in Egypt and Saudia Arabia respectively, preliminary data are being collected to elucidate effects, if any, of occupation, age, sex, rural or urban origin, geographical distribution, diet or previous parasitic infection on cancer frequency.

ETIOLOGY AND PROGNOSIS OF PLEURAL CALCIFICATION

T.J. Partanen, Inst. of Occupational Health, Dept. of Epidemiology & Biometry, *Haartmaninkatu 1, SF00290 Helsinki 29, Finland*

This project concerns the asbestos-related aetiology of pleural calcification and, from the view point of cancer, the prognosis of these calcifications. The study of prognosis has been directed mainly towards mortality from neoplasms in a cohort of 608 persons with pleural calcification and 608 persons without such calcification at the start of follow-up. The cohorts were formed in 1972 in connection with compulsory chest radiography of the populations of three communities: one with an anthophyllite mine and mill, the other with an asbestos cement plant and a third 'average' urban community. Persons working in these two plants have been identified. The cohorts were matched by age and sex and were between 20 and 74 years of age at that time. By the end of 1976, 18 deaths were observed from neoplasms in the calcification group, 14 in the reference cohort. For malignate neoplasms of the respiratory tract, the figures were 10 and 6, respectively, and, for the neoplasms of the lymphatic and haematopoietic system, 3 and 0. Follow-up will be extended at least until 1983.

EPIDEMIOLOGICAL STUDIES OF CANCER IN TWINS

I.V. Rantasalo, Helsingin Yliopisto, Dept. of Public Health Science, *Fabianinkatu 33, SF00290 Helsinki, Finland*

The study of twins can illuminate the relative role of different environmental factors in cancer etiology. The Finnish Twin Registry contains data on some 34,500 adult twins of the same sex. Zygosity was determined by questionnaire in 1975. Record linkage with the Finnish Cancer Registry for cancer incident prior to 1977 has been carried out. Since data on zygosity for many of the cases in this retrospective study were not available, cancer incidence in twins and risk of cancer among co-twins of cancer cases was compared for twins vs. non-twins using 7,332 singletons as controls. The study will be continued for several years until sufficient cases with data on

zygosity are available, as well as for study of specific sites.

A STUDY ON GASTRIC POLYPS

F.O. Laxen, Helsingin Yliopisto, Hospital Meilahti, Dept. of Medicine, *Haartmaninkatu 4, SF00290 Helsinki 29, Finland*

All cases with polyp-like lesions diagnosed by gastroscopy at the Gastroenterological Dept. of II. Medical Clinic, University of Helsinki, from 1970 onwards are included, reexamined and polypectomized as far as possible. The aim is to ascertain the risk of development of cancer in the polyp and in the surrounding mucosa. The morphological state of the gastric mucosa and the dynamics of gastritis often seen together with gastric polyps will be ascertained by taking multiple biopsies. The secretory state of the polypous stomach measured with serum gastrin and pepsinogen I levels will be investigated. The accuracy of cytological and biopsy specimens will be compared with the histological findings on polypectomy.

COMMUNITY EXPOSURES TO VINYL CHLORIDE MONOMER

R. Saracci, Centre International de Recherche sur le Cancer, Unit of Epidemiology & Biostatistics, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France*

A study is being undertaken of current (cross-sectional) mortality for the years 1947-1978 in the resident population of a town of 28,800 (1971) in which a large chemical factory is located. This factory has produced, among a variety of other chemicals, vinyl chloride monomer (VC) since about 1953 and discharge into the air occurs. Death certificates of residents are collected and coded (ICD-8) and a time trend analysis, by sex, age and cause of death, is being made in comparison with the corresponding time trends for the country as a whole. In addition time trends of proportional mortality by age, sex, cause of death and residential history within the town are computed. The study will be concluded, the analysis finished and paper prepared during 1980.

RISK OF PRIMARY LUNG CANCER AMONG IRON MINERS

C. Cavelier, Inst. Nacional de Recherche et de Securite, Service de Pathologie Professionelle, *Ave. de Bourgogne, Vandoeuvre-les-Nancy, 54500 Nancy, France*

The purpose of this study is to determine whether working in iron mines involves an increased risk of primary lung cancer. A retrospective mortality survey will be carried out in Lorraine on 2,000 miners for whom data from periodic medical examinations are available for a period of 20 years. The adjusted absolute and relative incidence rates for primary lung cancer among miners and surface workers will be compared.

EVALUATION OF EARLY DETECTION OF CANCER OF THE CERVIX UTERI BY CYTOLOGICAL SCREENING

D. Neuser, Staedtisches Krankenhaus im Friedrichsham, Zytodiagnostisches Zentrallabor, *Leninalle 49, 1017 Berlin, German Democratic Republic*

Between 1955 and 1969 the situation with respect to cervix carcinoma in Berlin hardly changed; morbidity, mortality, stage distribution and 5-year survival rates remained much the same. It is proposed to test whether cytological screening can lower morbidity and mortality. For this purpose, all women aged 20 to 65 living in Berlin will be cytologically examined every two years. Using the National Central Cancer Registry, the relationship of carcinoma in situ to invasive carcinoma and the stage distribution of the invasive cervix carcinomas and morbidity and mortality before, during, and after screening will be investigated. The first four years were characterized by a considerable increase in carcinomas in situ and a shifting of stages in favor of stages Ia and Ib, with coverage of 80% of the target population. In 1978 a significant decrease in carcinoma in situ (38%) and in invasive cervical cancer (30%) was observed for the first time in the whole female population.

HORMONAL CONTRACEPTION AS A FACTOR IN GYNECOLOGICAL CANCER

H. Radzuweit, Frauenklinik Bezirkskrankenhauses Cottbus, *Thiemstrasse 111, 75 Cottbus, German Democratic Republic*

Prolonged intake of hormonal contraceptives as a possible cause of increased risk for a gynecological cancer has been discussed many times. Several studies contradict this relationship. Using data from patients with colon, corpus uteri and ovarian carcinoma, this problem is again being analyzed for the period 1978-85. All female patients with carcinomas of these sites are being questioned about the period and the time they have taken contraceptives. Using controls, the frequency of intake of hormonal contraceptives in the total female population of this region will be deduced.

INTERNATIONAL HISTORICAL PROSPECTIVE STUDY OF HEALTH EFFECTS OF MAN-MADE MINERAL FIBRES IN THE PRODUCER INDUSTRY

R. Saracci, Centre International de Recherche sur le Cancer, Epidemiology & Biostatistics Unit, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France*

The objective of the study is to determine the mortality experience and, whenever possible, the cancer incidence of workers in the man-made mineral fibre (MMMF) production industry. Starting in 1976, factories belonging to the European groups of MMMF manufacturers (CIRFS-EURIMA) were individually visited to identify plants suitable for a historical prospective study, according to the following criteria: (1) No loss or destruction of personnal records; (2) MMMF production process in operation for at least twenty years; (3) some method of mortality/morbidity follow-up available; (4) nominal fibre-size of some fibres less than five microns. On this basis 13 plants, located in seven countries, were selected for study and data collection at these plants, in which workers exposed to MMMF total approximately 4,500, is starting in 1978. Environmental measurements of airborne MMMF concentrations are being carried out in parallel by a team from the Institute of Occupational Medicine, Edinburgh, U.K. Follow-up of the workers will be the responsibility of national collaborating institutions, and comparisons are to be made between groups of workers with various levels of exposure and between worker populations and general (national or regional) populations. All data will be finally submitted to a central, common analysis.

CASE-CONTROL STUDY - RELATION BETWEEN BREAST CANCER AND RESERPINE INTAKE

H.P. Kewitz, Freie Universitat Berlin, Inst. fuer Klinische Pharmakologie, *Hindenburgdamm 30, D1000 Berlin 45, Federal Republic of Germany*

Previous epidemiological retrospective studies established conflicting results about association between reserpine treatment and development of breast cancer.

In this country, where reserpine is the leading drug used in the treatment of arterial hypertension, this question deserved special attention.

We studied 512 cases with breast cancer, including all newly diagnosed women admitted at 17 hospitals in Berlin between 1975 and 1977. Controls matched for hospital and age were allocated to two groups: a) women with benign breast disease (n equals 878), and b) women admitted for surgery excluding breast or gall-bladder disease (n equals 392). Patients were interviewed for their medication histories with all participants ignorant about the final histopathological result at that moment. Information about medication was confirmed by written statements of the patients' physicians.

First results have been published - Europ. J. Clin. Pharmacol. 11, 79-83 (1977) and Naunyn-Schmiedeberg's Archives of Pharmacol. 308 supplement, R8 (1979) - and revealed no support to the hypothesis of association between reserpine treatment and breast cancer.

Final results, including stratification according to various known risk factors for breast cancer, histopathological classes, and duration of treatment will be published by this year.

STUDY OF OCCUPATIONAL CANCERS

L. Horbach, Friedrich Alexander Universitat zu Erlangen Nurenberg, Institut fuer Medizinische Statistik und Dokumentation, *Waldstr. 6, D8520 Erlangen, Federal Republic of Germany*

The aims of this study are: (1) to survey manual workers and other staff employed in chemical and related industries for cancer and (2) to analyze possible aetiological associations between different cancer sites and occupational chemical exposures. In this retrospective study of the years 1950-1968 all ill and/or deceased employees (active or retired) of 10 large firms have been included and for the same time period all other deaths from one of those firms also have been collected. Information has been collected on sex, cause of death, occupation, substance to which exposed and for the cases of cancer: type of neoplasm, age at time of diagnosis and method of diagnosis. For the statistical analysis a multivariate model is being used. In February 1979 a detailed description of the study (more than 400 pages) was presented; it should be discussed in several expert groups in April and in autumn 1979. The study will be published in 1980 in a research report of the DFG.

RELATION BETWEEN MEAT-CURING BY SMOKE AND FREQUENCY OF STOMACH CANCER

G. Hajdu, (No Performing Organization Reported), *Hungary*

In this area (Wend) it is traditional to smoke pork with freshly cut soft woods (alder, together with the fruit of the juniper bush). In such meat the amount of 3,4-benzpyrene is six times higher than in factory-smoked samples and other cocarcinogens have been found in these products. The farmers of Wend eat three to four times more of this meat than the average Hungarian, as do the Wends living in Solvenia near the Hungarian border. The frequency of stomach cancer has hitherto been twice as high among the population of Wend as among other groups living around this area. An educational campaign is expected to lead to a decrease in the frequency of this cancer in Wend.

CASE-CONTROL STUDY OF BREAST CANCER

Z. Pentek, Tolna County Hospital, Dept. of Radiology, *Beri-Balogh Adam 7/23, P.O.B 85, 7101 Szekszard, Hungary* (02423)

The aim of the investigation is to re-examine the high risk factors for breast cancer already established in the author's material. In two southern counties of Hungary, 511 breast cancer patients, both urban and rural, were re-investigated using a computer adapted questionnaire. Replies in the study were compared with those of an age-matched control group containing 942 women from the same geographical area without breast disease by using mathematical-statistical analysis (p equals 0.0; x2 equals 10.8). Significant risk factors were found to be almost the same as formerly: higher educational level (secondary school or more), blood relatives (mother and/or sister) suffering from breast cancer, nulliparae, first pregnancy after the age of 30, no suckling, some previous diseases such as struma, ovarian disorders and breast operation. A further study aims to determine the use of these factors for possible selection of a high risk group for breast cancer screening. 684 breast cancer patients and 15,571 screenees have been investigated. 81% of the cancer patients and 43% of the screened women were found to have one or more of the risk factors.

EPIDEMIOLOGICAL CUM-PREVALENCE STUDY OF CARCINOMA OF THE CERVIX IN URBAN, RURAL AND TRIBAL AREAS IN THE INDIAN POPULATION

C.A. Shah, Gujarat Cancer & Research Inst., Dept. of Gynecology, *New Civil Hosp. Campus Asarwa, Ahmedabad 380016, Gujarat, India*

Carcinoma of the cervix uteri is the most common cancer in Indian women. Through several studies in other parts of the world, the relationship of this cancer with low socioeconomic group, early onset of sexual activity and child bearing is well known. These factors are now being studied in a prospective study in urban, rural and tribal areas in the state of Gujarat, India. The clinical examination includes cytological smears and histological confirmation of suspected cancer. In the first part of the study some 30,000 women have been studied.

AN INTERVENTION STUDY OF ORAL CANCER AND PRECANCEROUS LESIONS IN RELATION TO TOBACCO USE IN RURAL INDIAN POPULATIONS

F.S. Mehta, Tata Inst. of Fundamental Research, Basic Dental Research Unit, *Homi Bhabha Rd., Bombay 400005, Maharashtra, India*

Through follow-up studies for the last ten years it has been established that tobacco usage in the various forms practiced in different parts of India is definitely associated with oral cancer and precancerous lesions. The incidence of precancerous lesions among those who do not practice tobacco habits of any kind was almost zero, whereas incidence among those with such habits ranged from 1 to 35 per 1,000 per year, depending upon the habit. The next step is to find out whether the association between oral cancer and precancerous lesions and tobacco habits is direct by demonstrating a reduction in the incidence of precancerous lesions when the tobacco habits are discontinued. A sample of 12,000 individuals with tobacco habits has been examined and interviewed in each of the three rural areas under

study. In order to persuade these villagers to give up their tobacco habits, they are being exposed to a concentrated program of education, motivation and guidance. The villagers are being shown a documentary film, especially made for this purpose, in the vicinity of their homes, in the most suitable format formulated after conducting impact studies of the film in each of the three areas. The message is also communicated personally to each of the examined individuals by trained social scientists. In addition, the population is being subjected to visual, audio and other media support in the form of newspaper articles, posters and radio broadcasts. These individuals are being reexamined annually to assess changes in tobacco habits, development of new oral precancerous lesions and changes in previously diagnosed lesions. The first annual reexamination is complete and the second one in progress.

MODIFYING EFFECT OF DIET ON UPPER ALIMENTARY TRACT CANCER IN PERSONS WHO CHEW AND SMOKE TOBACCO

P.N. Notani, Tata Memorial Center, *Dr. Ernest Borges Marg, Bombay 400012, Maharashtra, India*

Tobacco chewing and smoking habits carry a high risk for cancers of the upper alimentary tract, yet not all those who chew or smoke heavily contract the disease. This indicates a role for other factors which may have a modifying effect on these risks. Preliminary study of existing records of a Bombay population indicated a reduction in oral cancer risk in persons with tobacco chewing and smoking habits who ate eggs, meat or fish (Ind. J. Cancer, 13: 156-160, 1976). A pilot study was carried out to standardize the methods for collection of dietary information such as the type and quantity of Indian spices, consumption of vegetables, pulse and fat in addition to eggs, meat and fish. Data on habits and diet have been collected on cases and 167 controls during the current year. It is proposed to continue collection of data during 1980 following which the material will be analyzed.

EPIDEMIOLOGICAL STUDY OF CARCINOMA OF THE UTERINE CERVIX RELATED TO BATHING HABITS

M.S. Dvivedi, Cancer Hospital, *Indore 452001, Madhya Pradesh, India*

It is an established fact that carcinoma of the uterine cervix is more prevalent in low socioeconomic groups even in developed areas. There is a possibility that low socioeconomic groups do not have proper washing facilities in their dwelling places. It is presumed that women who submerge the pelvis in a bath tub might cleanse the vaginal passages more effectively than those who take a shower. In India it is rare to have a bath tub in the bathroom even in the urban population. The usual method of taking a bath is by a bucket and mug. In the rural areas the source of water is either tanks, rivers or rivulets and either the women bathe at their own house using a bucket and a mug or at these other sources of water. In the present study we are studying habits of patients reporting with carcinoma of the uterine cervix for treatment at this center. We are also studying the bathing habits of the husbands of the patients with particular reference to circumcision, retraction of the prepuce during washing and cleaning smegma. This study has been undertaken with a view to studying the status of genital hygiene of patients with carcinoma of the uterine cervix. The non-circumcised husbands are questioned to determine how often they remove the smegma when taking a bath. The distributional pattern of the patients according to these habits may give some indication of causative factors of this disease.

NATURAL BACKGROUND RADIATION AND CANCER FREQUENCY IN HUMAN POPULATION GROUPS

S.P. Allwright, University of Dublin Trinity College, St. James Hospital, Dept. of Community Health, *James St., Dublin 8, Ireland*

Studies investigating the relationship between natural radiation and cancer have produced varying and inconclusive results. The objective of this study is to determine type specific age standardized cancer death rates in Ireland in relation to defined areas of high and low background radiation. Regions of probable high and low radiation have been selected on the basis of existing geological data. Radiation levels both indoor and outdoor, in these areas will be monitored. The unit area for radiation monitoring will be ten sq km, based on the National Reference Grid. Cancer mortality in the regions where radiation has been measured will be determined, also based on the ten sq km unit of area.

CASE-CONTROL STUDY OF CANCER OF THE URINARY TRACT IN THE PROVINCE OF TORINO, ITALY

B. Terracini, Universita degli Studi di Torino, Istituto di Anatomia e Istologia Patologica, *Via Santena 7, I10126 Turin, Italy*

A case-control study on cancer of the urinary tract in male residents in the Province of Torino started late in 1977. Cases are collection in three of the eight urological wards in hospitals (or University departments) of the Province of Torino. Each case is sex- and age-matched with a control, hospitalized in the same urological wards. All cases of cancer, cystitis and hematuria of unknown origin are excluded as controls. Information is collection on smoking experiences, coffee consumption, use of analgesics and artificial sweeteners and occupational history throughout life. Up to December 1979, 191 cases and 175 controls had been interviewed. Preliminary results on 75 pairs have been published (Epidemiologiae Prevenzione, 1979). Further analysis will be carried out when 200 pairs have been collected.

MORTALITY, INCIDENCE AND PREVALENCE AS INDICATORS OF THE MAGNITUDE OF THE CANCER PROBLEM WITHIN AN ITALIAN REGION

V. Mastrandrea, Universita degli Studi di Camerino, Inst. of Hygiene, *62032 Camerino, Italy*

Within the Marche region, located in Central Italy, as within most of the country, there is heterogeneity as far as demographic, socio-economic and environmental characteristics are concerned. Taking into account these considerations, the geography of Marche and the findings of a previous study, an investigation will be carried out for the period 1971 to 1981 into the distribution of mortality, incidence and prevalence by individual tumor sites in the coastal, hill and mountain zones of this region which can be respectively considered urban, semi-urban and rural. The three zones may represent an ideal compromise between the need for units small enough to be homogenous for demographic and environmental characteristics that might influence cancer risk and yet large enough to provide stable estimates. Mortality, incidence and prevalence data are abstracted from death certificates from the 246 municipalities of the Marche region and from the clinical record cards available in the 90 hospitals of the same region.

CANCER MORTALITY AMONG ATOMIC BOMB SURVIVORS IN HIROSHIMA PREFECTURE

M. Kurihara, Hiroshima University, Research Inst. of Nuclear Medicine & Biology, Dept. of Epidemiology & Social Medicine, *1-2-3 Kasumi Minami-Ku, Hiroshima 734, Hiroshima, Japan*

The atomic bomb survivors in Hiroshima Prefecture were estimated in 1975 to be nearly 180,000. Using the data bank containing information about the survivors in our institute, a survey on cancer mortality among the survivors from 1965 onwards is being conducted. This includes comparison with mortality in the general population of all Japan and in the non-exposed population of Hiroshima Prefecture. The mortality statistics for 1968, 1969 and 1970 will be obtained in 1979.

MORTALITY STUDY OF STEEL WORKERS

K. Nakamura, National Inst. of Industrial Health, Dept. of Industrial Epidemiology, *2051 Kizuki Sumiyosityo, Kawasaki, Kanagawa, Japan*

Excesses of respiratory cancer among coke oven workers are considered to be related to the exposure to coal tar effluents. To study whether there are any other carcinogenic risk factors in the environment of iron and steel producing plants, about 300,000 steel workers who had worked for at least 1 year at the beginning of 1973 in one of 127 plants in Japan were registered as members of the study cohort. Ascertainment of deaths will be obtained from the family registry system in Japan and death certificate information will be collected from the District Legal Affairs Bureau. In a preliminary stage, the cohort will be followed up retrospectively to the end of 1976, but follow-up thereafter will be continued.

STUDY OF NUTRITION, STEROID METABOLISM AND THE INCIDENCE OF FEMALE CANCER

M. Kodama, Aichi Cancer Center Research Inst., Dept. of Chemotherapy, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan*

In various ethnic groups the risk of developing breast cancer is often inversely related to that for cervical cancer. The hormonal environment of the host may somehow be implicated in the induction of these cancers. The relation between the nutritional level, steroid metabolism and the incidence of cervical and breast cancers will be investigated among the inhabitants of urban and rural districts of Japan. The characteristics of patients with such neoplasms will be compared with those of populations with differing cancer risks. The steroid metabolism of each subject will be assessed by estimating the excretions of 14 neutral steroids with 24 hr. urine. Initial results have been published in the Journal of the National Cancer Institute (54:1023-1029, 1975; 54:1275-1282, 1975; 54:41-47, 1977 and 59:49-54, 1977, and 61:35-39, 1978).

EPIDEMIOLOGICAL STUDY OF BLADDER CANCER

Y. Ohno, Nagoya University, School of Medicine, Dept. of Preventive Medicine, *65 Tsurumai-cho, Showa-ku, Nagoya 466, Aichi ken, Japan*

In Japan, the age-adjusted mortality rate for bladder cancer has levelled off in males and there is a possible downward trend for females over the last two decades. These trends were observed despite the recent remarkable increases in potentially hazardous environmental agents. In addition, the proportion of bladder cancer and kidney cancer deaths has been constant, 7:3, over these 20 years. These findings are very suggestive of the aetiological importance of host factors in bladder cancer production. Host factors and several environmental factors are now being investigated accordingly in Metropolitan Nagoya by a case-control study. Along with this investigation, familial cases are compared with non-familial cases in respect to tryptophan metabolism, HL-A types and others. Geographic clusters of bladder cancer deaths by city and county have been tested by a newly developed significance test, based on a Monte Carlo method. The test revealed no significant clusters of either high or low bladder cancer mortality in Japan from 1969-1971.

MALIGNANT NEOPLASMS OF THE GALLBLADDER AND BILE DUCTS IN JAPAN

S. Tominaga, Aichi Cancer Center Research Inst., Division of Epidemiology, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan*

This study aims to describe geographical distribution and time trends of malignant neoplasms of the gallbladder and bile ducts in Japan and to discover etiological factors by relating various environmental factors and other related diseases to mortality from biliary tract cancer. Analysis comparing mortality rates from malignant neoplasms of the gallbladder and bile ducts and food intake by prefecture suggests that dried noodles, pork and fish might be associated with this cancer. Relationships between biliary tract cancer and gallstones and other biliary tract diseases are now under investigation using autopsy materials.

ESTIMATION OF CANCER INCIDENCE IN ALL JAPAN

I. Fujimoto, Center for Adult Diseases, Dept. of Field Research, *3-3 Nakamichi 1-Chome, Higashinari-ku, Osaka 537, Japan* (D-IARC-79-375)

In order to obtain comparable cancer data in various areas of Japan and to estimate cancer incidence in all Japan, a co-operative cancer incidence survey has been conducted five times since 1973 with the participation of all active cancer registries in Japan. In 1978, twelve prefecture-wide and two city-wide registries took part. Each registry prepared the data according to standard methods as far as possible. From these data, age-adjusted incidence rates were computed for each prefecture or city and the cancer incidence for all Japan estimated at the Osaka Cancer Registry. The survey will be conducted yearly.

SURVIVAL OF CANCER PATIENTS IN OSAKA

A. Hanai, Center for Adult Diseases, Dept. of Field Research, *3-3 Nakamichi 1-Chome, Higashinari-ku, Osaka 537, Japan* (01029)

In Japan, the five-year survival rates of cancer cases for the general population were first ascertained in Osaka. The five-year relative survival rates for cases diagnosed as cancer during 1965-1974 were calculated using registry data linked with a file of all the death certificates for Osaka residents during 1965-1979. In Osaka between 1965-1970 and 1970-1974, survival rates rose, Particularly for stomach, large intestine, breast, uterus, and bladder cancer, malignant lymphoma and leukemia. Differences in survival rates between different districts within Osaka will be analyzed.

EPIDEMIOLOGICAL STUDY OF THE NATURAL HISTORY OF STOMACH CANCER

A. Oshima, Center for Adult Diseases, Dept. of Field Research, *3-3 Nakamichi 1-Chome, Higashinari-ku, Osaka 537, Japan*

A prospective study is being conducted to estimate the frequency of the development of cancer in persons found to have gastric ulcer, gastric polyp and chronic gastritis. From a follow-up study of the 1,782 patients diagnosed through a screening program as having gastric ulcer, it was shown that there were 30 cancer cases during the follow-up period (average 5.1 years) in contrast with the expected number of 15.5. About half of the 30 cancer cases, however, were diagnosed as cancer within a year of the diagnosis of gastric ulcer and should have been considered as false negative cases. These data suggest that those patients with a diagnosis of gastric ulcer should be regarded as a high risk group, although a hypothesis of the malignant change of gastric ulcer is not supported. A follow-up study of about 10,000 patients on whom endoscopic biopsy tests were conducted at this Center and whose diagnoses were histologically confirmed is now being prepared.

ETIOLOGICAL FACTORS OF HEPATOCELLULAR CARCINOMA IN CHINESE AND ABORIGINES OF WEST MALAYSIA

E. Sumithran, Universiti Malaya, Medical Faculty, Dept. of Pathology, *Pantai Valley, Kuala Lumpur, Malaysia* 2211

Liver cancer is one of the most common malignancies in Malaysia occurring frequently among the Chinese and Orang Asli (aborigines). Necropsy and liver biopsy specimens showing hepatocellular carcinoma are examined by orcein, immunoperoxidase and immunofluorescence for the presence of HBA. Patients with liver cancer are examined for HBsAg. Each Orang Asli patient admitted to the Gombak Orang Asli Hospital is accompanied by other members of his family. The blood of these persons, who constitute a control group, is examined. Chronic liver disease associated with the hepatitis B antigen seems to be an important factor in the etiology of liver cancer in the Orang Asli. It is proposed to examine the food eaten by the Orang Asli for aflatoxin.

INCIDENCE OF DIFFERENT HISTOLOGICAL TYPES OF STOMACH CANCER IN WARSAW

Z.L. Wronkowski, Instytut Onkologii im Marii Sklodowskiej Curie, Dept. of Cancer Control & Epidemiology, *15 Wawelska St., 00973 Warsaw, Poland*

There are conspicuous differences in the incidence of stomach carcinoma in different populations. Stomach cancer still remains a leading malignancy in Poland and the high incidence rates could be caused by changes in diet during the second world war and the post-war period. The main objectives of the present study are to investigate the distribution of two types of stomach carcinoma, i.e. 'intestinal' and 'diffuse', in the population of the city of Warsaw and to analyse the time trends for three decades. The study design is retrospective. All available pathological slides for stomach cancer patients from the city of Warsaw will be collected and reviewed. Age-adjusted rates will be computed.

CANCER INCIDENCE AMONGST PETROCHEMICAL WORKERS IN WARSAW REGION

Z.L. Wronkowski, Instytut Onkologii im Marii Sklodowskiej Curie, Dept. of Cancer Control & Epidemiology, *15 Wawelska St., 00973 Warsaw, Poland*

The purpose of this study is to determine whether incidence of cancer among petrochemical workers differs from the rates in two control groups, i.e., farmers and the general population in the Warsaw region. The population under study consists of all workers of the Petroleum Plant in Plock who started work after January 1, 1965 - approximately 15,000 individuals. A control group of farmers, individually matched by year of birth and sex, will be used. Both groups will be followed up and cancer cases will be ascertained through linkage of records of the study and control groups and those of the Warsaw Tumor Registry. Data on risk factors for study and control groups will be collected. Age, by individual year, sex and site specific cancer incidence rates will be compared with the expected numbers based on incidence rates in the Warsaw region. Man years of exposure will be calculated for specific cohorts by age and sex so that a dose-response relationship may be tested.

EPIDEMIOLOGICAL FACTORS IN GASTRIC CANCER, CLUJ DISTRICT, ROMANIA

G. Bolba, Oncological Inst. of Cluj-Napoca, Dept. of Epidemiology & Statistics, *Republicii Nr. 34-36, R3400 Cluj-Napoca, Romania*

Study of cancer incidence in the Cluj district (1974-1975) shows that in males gastric cancer is the most common form of cancer (42.2 per 100.000 per annum being more widespread in the rural areas (about 73.0). In females, breast cancer is the most common form of cancer (27.0) followed by cervix uteri (23.8) and stomach (22.1). Previously, the rank order was cervix uteri, stomach, cancer. The correlation between nitrosamines and gastric cancer is being studied, estimating the secondary amines in traditional foodstuffs and the nitrate and nitrite in drinking water in rural areas. Routine systematic investigations of pollution in drinking water in the Cluj district show considerable variations.

COHORT STUDY ON HEPATITIS B CARRIERS AND LIVER CANCER

W.O. Phoon, University of Singapore, School of Medicine, Dept. of Social Medicine & Public Health, *Sepoy Lines, Singapore 3, Singapore*

Liver cancer is one of the most common forms of cancer in Singapore, especially among Chinese males. Seroepidemiological studies have shown that the frequency of exposure to hepatitis B virus (HBV) and the frequency of chronic carriers is much higher among liver cancer patients than among controls. The main objectives of the present study are to identify the carriers and non-carriers of HBV and to measure their risk for developing liver cancer. A group of at least 5,000 Chinese males over 45 years of age will be bled and their sera will be tested for various markers of HBV. Re-bleeding of those patients found to be positive for various markers of HBV will be attempted to confirm their carrier status. The liver cancer cases which develop in this cohort will then be identified by record linkage with the National Cancer Registry in Singapore. In addition, an attempt will be made to study the other epidemiological factors which may have a bearing on the onset of liver cancer. The study design is prospective by nature.

ENVIRONMENTAL AND DEMOGRAPHIC STUDIES ON ESOPHAGUS CANCER IN TRANSKEI

S.J. Van Rensburg, South African Medical Research Council, National Research Inst. for Nutritional Diseases, Division of Nutritional Pathology, *P.O. Box 70, Tygerberg 7505, Cape Province, South Africa*

Esophageal cancer shows a marked geographical variation in incidence in the Transkei. Three main lines of investigation are being undertaken: 1) Agricultural associations: the following studies are being conducted on a broad scale in high and low incidence districts; soil profiles and pedalogical classification, soil mineral and trace elements, elements in plants and water and the distribution of mycotoxin in edible produce. 2) Environmental carcinogens: analyses of nitrosamines in prepared food and beer from high and low incidence areas, mycotoxin analyses of prepared and stored food from high and low incidence areas, biological screening program of dietary staples, snuff, beer and home-grown tobacco smoke condensate on rats. 3) Population studies: case-control questionnaire study, a clustering study -geographic, temporal and familial - and detailed ecological studies in cluster and adjacent areas free of esophageal cancer.

RETROSPECTIVE STUDY OF CANCER MORTALITY RELATED TO PLACE OF RESIDENCE

C. Schlatter, Eidgenossische Technische Hochschule Zurich, Inst. for Toxicology, *Schorenstrasse 16, 8603 Schwerzenbach, Switzerland*

It was shown by Blumer (Schweiz. Med. Wschr. 106, 503 (1976)) that cancer mortality was strongly dependent on place of residence. People living in the immediate vicinity of the central road of a city in Switzerland died about 9 times as frequently from cancer as people in remote areas of the same city. In a recalculation of the raw data (Schweiz. Med. Wschr. 107, 312 (1977)) the results were confirmed in that the cancer mortality of the group living near the road was higher by a factor of two than expected on the basis of age-adjusted cancer mortality in Switzerland. It is planned to determine if a similar relationship can be found in other places in Switzerland.

CHRONOLOGICAL OBSERVATION OF EPIDEMIOLOGICAL CHARACTERISTICS OF LUNG CANCER IN TAIWAN

S.P. Yang, National Taiwan University, College of Medicine, Dept. of Internal Medicine, *1 Jenai Rd. Section 1, Taipei, Republic of China*

A previous study indicates that lung cancer in Taiwan has the following epidemiological characteristics: 1. An increasing rate which is the highest among malignant neoplasms in the past 20 years. 2. A male to female ratio of 2 to 1, which has been the same for the past 30 years. 3. A high frequency of adenocarcinoma even in males (34.3% for males and 58.7% for females). 4. A recent rapid increase which cannot be explained solely by cigarette smoking. In order to determine whether these epidemiological characteristics will change in the future, a time trends study is underway for each five-year interval, analyzing available vital statistics data and clinical material collected from major hospitals islandwide (there is still no islandwide cancer registration system) and comparing the results of the 2nd lung cancer prevalence survey (in conjunction with the 5th tuberculosis prevalence survey) in 1977-1978 with those of the first survey carried out 5 years ago.

3.1559,
BURKITT'S LYMPHOMA PROJECT, MARA REGION, TANZANIA

G.R. Brubaker, Shirati Mission Hospital, *Musoma, Tanzania*

The general objective is to study the epidemiology of Burkitt's Lymphoma (BL) and, more specifically, to investigate the role of hyper-endemic malaria in BL causation. In order to see whether hyper-endemic malaria is necessary for BL development, a malaria suppression trial is being carried out. Chloroquine tablets are distributed twice monthly to approximately 90,000 children aged 0-10 in order to reduce malaria to hypo-endemic levels. The malaria suppression was initiated in 1977 and will be continued for five years, during which the incidence of BL will be carefully monitored in the area. The prevalence of malaria parasitaemia declined satisfactorily during the first year of the trial but since the end of 1978 it has returned to the previous high levels. Drastic measures are now being taken to rectify this situation. The program will continue until the end of 1982.

ENDEMIC PLEURO-PERITONEAL DISEASE IN RURAL TURKEY

Y.I. Baris, Hacettepe Universitesi, Faculty of Medicine, Dept. of Chest Diseases, *Ankara, Turkey*

Recent clinical and epidemiological studies in Turkey have revealed that calcified pleural plaques, chronic fibrinous pleurisy and malignant mesothelioma are endemic in some villages with asbestos deposits. Mineralogical electron microscopy studies in airborne dust samples in these villages revealed mostly tremolite, chrysotile asbestos and other mineral fibers (rutile, eckermannite, antigorite etc.). However, there are two villages in the Nevsehir region without asbestos deposits which have a much higher incidence of the same diseases. Mineralogical studies of some geological and airborne dust samples and studies of lung tissues have demonstrated the presence of erionite, a type of zeolite. Part of the study has been published.

3.1561,
AN EPIDEMIOLOGICAL STUDY OF LEUKEMIA INDUCED BY EXPOSURE TO DIFFERENT CHEMICALS

M.B. Aksoy, Istanbul Universitesi, Faculty of Medicine, Internal Clinic, *Bayezit, Istanbul, Turkey*

Despite the fact that there is a significant reduction in the incidence of haematopoietic insults, such as aplastic anaemia and leukaemia, after the strict prohibition of the use of benzene as a solvent in Turkey, other chemicals (those used in the textile industry and asbestos) may still be involved in the occurence of leukaemia among the working population. The scope of the present project is to perform an epidemiological study as well as clinical and laboratory investigations directed towards the detection of the incidence and the types of leukaemia produced in those chronically exposed to these chemicals. It is also believed that the detection of the patients involved, while they are still at the pre-leukaemic stage, may be of importance. The cytochemical and immunological alterations likely to be observed in such subjects constitute another interesting aspect of the task. Chromatographical analysis of the chemicals in question will be undertaken.

3.1562,
PROSPECTIVE STUDY OF BURKITT'S LYMPHOMA, WEST NILE DISTRICT, UGANDA

G. Olwitt, East African Virus Research Inst., *P.O. Box 369, Arua, Uganda*

The main objective is to study the etiological involvement of the Epstein-Barr virus (EBV) in Burkitt's lymphoma (BL). Additional objectives are to study the epidemiology of the EBV and BL in the West Nile district, and the role of hyperendemic malaria in BL causation. cohort of 42,000 children aged 0-8 years was bled in an initial phase between 1972 and 1974. During the subsequent case detection, fourteen BL cases were diagnosed in the children who were bled. The testing of the 'pre-sera' and appropriate controls showed that viral capsid antigen antibodies to the EBV had already been elevated in the BL candidates up to four years before tumor manifestation (Nature 274, (5673) 756-761, 1978). Other EBV antibody activities (early antigen and Epstein-Barr nuclear antigen) were not elevated in the pre-BL sera and the case detection in the study cohort will continue until 1979 in order to study the mechanism of how EBV infection promotes BL development. The study of BL epidemiology has confirmed that the tumor still shows significant time-space clustering and seasonal variation, thus favoring an infectious etiology. The epidemiology of the EBV is being studied in number of sample groups which were bled repeatedly during the years 1973-1977. The testing for EBV antibodies in the sera is now progressing at the laboratory at IARC, Lyon. The BL case detection in the West Nile district will continue through 1979. Since the testing of the 14 pre-bled BL sera in 1977, 5 new pre-bled BL cases have been detected and will be tested for anti-EBV activities in 1979. The analysis of the malaria data collected in the longitudinal survey in the West Nile has indicated that malaria parasitemia declined drastically in the West Nile between 1973 and 1977. The malaria slides are now being reexamined to ensure that this observation is true.

3.1563,
STUDY OF A BRITISH SHIPYARD POPULATION WITH REGARD TO LUNG CANCER INCIDENCE IN MEN WITH PLEURAL PLAQUES

J.R. Edge, University of Newcastle Upon Tyne, Postgraduate Department, *6 Kensington Terr., Newcastle Upon Tyne NE1 7RU, United Kingdom*

Pleural plaques, both fibrous and calcified, have been widely described in the neighborhood of asbestos mines and in populations using asbestos industrially. They are commonly thought to be benign lesions merely indicating prior asbestos exposure. The present study concerns shipyard population of 7,000 men who have been found to have a high prevalence of pleural plaques (one third of the male population as assessed in 100 consecutive unselected autopsies), and a substantial annual incidence of malignant mesothelioma of the pleura. The clinical impression is that the occurrence of bronchial carcinoma in men showing pleural plaques is substantially increased. A group of Barrow shipyard workers with pleural plaques and a matched group of Carlisle workers from different but non-asbestos-exposed occupations are being compared in a long-term mortality study. The results to date suggest an increased incidence of bronchial carcinoma in the men with pleural plaques of approximately five times that found in the control series. After elimination of the subjects showing bias, due to being obtained from clinic sources, a residual group of 231 subjects with plaques from Barrow, together with a matched group of 231 controls from Carlisle, has been flagged on the National Cancer Registry computer in Southport. Both groups will be followed for not less than five years unless a valid result emerges sooner. The increase in the incidence of bronchial carcinoma in the plaque group after this has been allowed for, is likely to be nearer twofold than the fivefold initially estimated.

LONG-TERM FOLLOW-UP OF ALL WORKERS EXPOSED TO ASBESTOS IN NORTHERN IRELAND

J.H. Langlands, Belfast City Hospital, Respiratory Investigation Centre, *93 Lisburn Rd., Belfast BT9 7AB, United Kingdom*

The objectives are to see how the changing conditions of work with asbestos are affecting the incidence of asbestosis, carcinoma of the lung and mesothelioma and whether preventive measures being taken are effective. This is a continuation of work already published and entails examining all men still at work and all men who have worked with asbestos in the past at 2-3 year intervals. If they develop illnesses or die, every effort is made to document precisely the nature of the illnesses or cause of death.

CARDIFF CERVICAL CYTOLOGY STUDY

J.B. Landsman, Medical Research Council, Epidemiology Unit, *4 Richmond Rd., Cardiff CF2 3AS, Wales, United Kingdom*

The main objective of the Cardiff Cervical Cytology Study is to evaluate screening for cervical cancer. The study is based on a defined population: all women who have ever been married, aged 25-69, resident within the Cardiff City area. The basic design objective was that all eligible women should be screened three times. The defined population was enumerated by house-to-house visiting, and eligible women were offered appointments for a cervical smear test at specially organized clinics. The study

began in late 1965 and the first round of visiting the city finished early in 1971. The defined population numbers some 71,000 women of whom 46,000 (65%) accepted the offer of the test. Subsequent to the first smear women were re-called for second and third smears at two to three yearly intervals. Some 38,000 have so far had second smear and over 30,000 have had a third. The study should provide estimates of the prevalence and incidence of the various pathological states, and estimates of false negative and false positive error rates. Death and registration rates for invasive cancer in the Cardiff City area are being monitored.

NATIONAL REGISTRY FOR RADIATION WORKERS

J.A. Reissland, National Radiological Protection Board, Dept. of Physics, *Harwell 0X11 ORQ, Didcot, United Kingdom*

The purpose of this study is to investigate by long-term follow-up studies any relationship between occupational exposure to radiation and age-specific causes of death. Any worker who is monitored regularly for exposure to radiation and for whom dose records are kept is entered in the Registry. It is expected to include over 50,000 current workers in addition to those who leave the industry whether by death, retirement or change of job. Once sufficient data on mortality has accumulated, periodic analyses will be carried out with several different control groups chosen from among those workers on the Registry with very low lifetime radiation doses.

THE EFFICIENCY OF CERVICAL CANCER SCREENING IN WEST YORKSHIRE

D.M. Parkin, Leeds Area Health Authority, *Claypit Ln., Hepworth House, Leeds LS2 8AP, England, United Kingdom*

The project covers areas of West Yorkshire with varying levels of the incidence of cervical cancer and aims to collect data on a 1:10 sample of all cervical smear examinations performed, with follow-up on all abnormal tests. Incidence data for clinically manifest carcinomas will be obtained from the Cancer Registry. Information on levels of screening, together with the results in the population studied, will be available for comparison with data collected elsewhere. It is intended to mount intervention studies to influence the degree and location of screening, with simultaneous monitoring of the results obtained.

EPIDEMIOLOGICAL STUDIES OF THE RELATIONSHIP BETWEEN RE-USE OF WATER AND HAZARDS TO HEALTH

S.A. Beresford, University of London, Royal Free Hospital School of Medicine, Dept. of Clinical Epidemiology & Social Medicine, *8 Hunter St., London WC1N 1BP, England, United Kingdom*

The aim of the studies is to investigate the effects on the health of populations of drinking water derived from water sources contaminated with domestic and industrial waste, with particular reference to cancer of the digestive system, and of the genitourinary system. The first stage of the studies is to examine the association between cancer mortality and the source of water supply in terms of the history of pollution and degree of re-use. The hypothesised association arises mainly from the Mississippi River study although other studies have also examined this association. Possible disease outcomes other than cancer will also be investigated to provide a basis for formulating further hypotheses.

GASTRIC CANCER AND NITRATE INGESTION - NITRATE IN DRINKING WATER

P.M. Fraser, University of London, London School of Hygiene & Tropical Medicine, Dept. of Epidemiology & Medical Statistics, *Keppel St., London WC1E 7HT, England, United Kingdom*

Evidence is accumulating that populations ingesting large amounts of nitrate have a high mortality from cancer, particularly of the stomach, due to the formation in vivo of carcinogenic nitrosamines. Nitrate levels in some water sources in the eastern regions of England are rising steadily due to extensive use of fertilizer. Mortality from gastric cancer within these regions in 1969-73 is being examined in relation to the nitrate concentration in drinking water 15 to 20 years previously. The objectives of this study are: 1) to establish whether there is an increased risk of gastric cancer in populations exposed to moderately high levels of nitrate in drinking water and 2) to determine a safe level for nitrate in drinking water.

GLOUCESTERSHIRE STUDY

P.N. Lee, (No Performing Organization Reported), *United Kingdom*

In 1963-1967 information on respiratory symptoms, residential, occupational and medical history, as well as full details of smoking habits, was obtained from 2,377 people in hospitals in Gloucestershire. Those selected formed six groups, namely lung cancer, chronic bronchitis, other chest diseases, cardiac, orthopaedic and other cancer cases. Between 1974 and 1977 an attempt was made to reinterview those still alive and to determine their current smoking habits and respiratory symptoms and to find the cause of death of those who had died. In addition a sample of the living population in Gloucestershire in 1974 was interviewed to determine their smoking habits and respiratory symptoms. The data is now being analysed with four main objectives. Firstly, to determine how the six hospitalized groups differed on factors recorded on the original questionnaire. Secondly, to determine within disorder groups how survival is related to the information recorded originally. Thirdly, to test how representative the survivors are of the living population in Gloucestershire. Fourthly, to investigate changes in symptoms and in smoking habits in the survivors and examine how the progression of the former is related to changes in the latter.

INCIDENCE OF BREAST CANCER IN WOMEN WHO HAVE HAD A TOTAL COLECTOMY AT AN EARLY AGE

E.H. Rang, University of London, St. Georges Hospital Medical School, Dept. of Surgery, *Cranmer Terr. Tooting, London SW17 0RE, England, United Kingdom*

There is a high correlation between the intake of dietary fat and the incidence of cancer of the colon and breast. It has been suggested that the amount of dietary fat affects the composition of the gut flora and the concentration of biliary steroids in the gut and that certain bacteria might be able to produce carcinogens in the colon from these steroids. The production by intestinal bacteria of steroidal oestrogens from the biliary steroids has also been demonstrated and suggests a possible role for these bacteria in breast cancer. The purpose of this study is to test the possibility of a relationship between the production or modification of oestrogenic steroids by gut

bacteria and the development of breast cancer by seeing whether there is a decreased incidence of breast cancer in women who have had a total colectomy at an early age. It is hoped to follow up about 2,000 women who had a total colectomy and compare the observed number of breast cancers in the group with the number expected if their colons were retained.

EPIDEMIOLOGICAL ASPECTS OF HODGKIN'S DISEASE IN GREATER MANCHESTER

I. Leck, Christie Hospital & Holt Radium Inst., Regional Cancer Epidemiology Unit, *Wilmslow Rd., Withington, Manchester M20 9BX, England, United Kingdom*

The hypothesis that Hodgkin's disease is transmissible is being explored in two ways. (1) The importance of a recent report that links such as having attended the same school or work place are no more common between Hodgkin's disease cases than between controls (Smith et al., Lancet 1977, II, 59) is being assessed by seeing whether excesses of such links can be demonstrated between either infectious hepatitis or infectious mononucleosis patients who have been in hospital. (2) Fifteen years cases of Hodgkin's disease in Greater Manchester are being tested for space-time interaction by Knox's method, in order see whether there is any tendency for patients who live close together to develop symptoms either at around the same time or (as might be expected if there was a long incubation period) at intervals of a particular length.

AN EPIDEMIOLOGICAL STUDY OF STOMACH CANCER IN NORTH STAFFORDSHIRE

C.A. Veys, North Staffordshire Medical Inst., Industrial & Community Health Research Centre, *Hartshill, Stoke on Trent ST4 7NY England, United Kingdom*

The mortality from stomach cancer in Stoke-on-Trent is one of the highest recorded in the United Kingdom, but the reasons for this are unknown. Some positive associations between stomach cancer and occupation have been observed, in particular with certain dusty trades; and there is also an association with suspended particulate air pollution. For many years in the past, the North Staffordshire area has been noted for its high level of air pollution, which was predominantly caused by smoke emission from local major industries, especially pottery manufacture. Coal mining also predominates and there are many other dusty occupations. The main objective of the study, which is in two parts, is to examine whether occupational factors (especially dust exposure) play a part in the aetiology of stomach cancer in the Stoke-on-Trent area. The investigation will encompass firstly a detailed examination (in epidemiological terms) of each case of stomach cancer (both male and female) that occurred in the County Borough District of Stoke-on-Trent within the fifteen year period 1961-1975. In addition, prospective case-control study on each person newly presenting with stomach cancer within the succeeding three years (beginning in 1977) will be undertaken. A detailed whole life occupational history will be obtained at interview and matched against that obtained from four controls chosen at random from the population at large. The data will be compared and contrasted for statistically significant differences in the dust exposure between cases and control groups.

LUNG CANCER IN THE ANTIMONY INDUSTRY

J.P. Cunningham, Anzon Ltd., *Cookson Hse. Willington Quay, Tyne & Wear, Wallsend NE28 6UQ, England, United Kingdom*

A prospective epidemiological survey of workers engaged in the production of antimony metal, antimony oxide, and antimony sulphide is being undertaken to ascertain whether there is an excess of lung cancer by comparison with local death rates and death rates in other occupations. The survey includes all persons working at the plant on 1/1/1961 or joining after that date, and is likely to continue until 1985 or later. Persons leaving employment are traced. The calculations of expected deaths are age-specific and related to man-years of exposure. The survey covers an adjacent zircon plant, as a control. Other factors studied are smoking, sulphur, arsenic and area of residence.

BREAST CANCER AND ORAL CONTRACEPTIVES

D.T. Janerich, State Bureau of Cancer Control, *Empire State Plaza, Tower Bldg. Rm. 565, Albany, New York* 12237

This case-control study was designed to study the possible relationship between oral contraceptives and breast cancer. Our case group consists of women of 45 years of age or younger with breast cancer; controls are matched on the basis of age at first birth. The final case group will consist of 300-400 women. The questionnaire is self-administered and requires full contraceptive and reproductive histories. This study is nearing the end of the data collection stage. The association of prior benign breast disease and oral contraceptive use with breast cancer is currently being analyzed. Family history and oral contraceptive use in relation to breast cancer is also being examined.

URANIUM EPIDEMIOLOGY STUDY

R.W. Buechley, University of New Mexico, School of Medicine, Epidemiology Section, *University Hill N.E., Albuquerque, New Mexico* 87131

4,071 uranium miners with at least one year's underground experience since 1957 in the Grants, New Mexico uranium belt will be studied to examine health effects of low level radiation exposures for which only extrapolations are now available. Since mining in this district began, precision of radiation measurement and stringency of radiation standards have increased. Of the 4,071 miners in the study, 1,800 started work before 1961, at mean radiation levels near 40 working level months (WLM) per year. Another 1,300 started in 1961-1970, at mean radiation levels declining over the years from 40 to 4 WLM per year. The remainder started in 1971 or later, at mean radiation levels of 2.5 WLM per year and not exceeding the allowable 4 WLM per year. Standard physical examinations, with cigarette smoking and previous mining histories, are available from the beginning. Of the 139 miner deaths reported to date, 84 were from accidents, poisonings or violence. Of the 55 other deaths, 22 were due to lung cancer, all in miners employed before 1961 in Grants or elsewhere and concentrated in miners with over 200 cumulative WLM. 20 of the 22 lung cancer deaths were in cigarette smokers. Proposed work for 1980-1981 includes determining current status of miners through the US Social Security Administration, etc., refining their amounts of radiation exposure, and planning a very long-term cohort study.

3.1586,

HEALTH OF FORMER THORIUM WORKERS

A.P. Polednak, Argonne National Lab., Division of Biological & Medical Research, *9700 S. Cass Ave., Argonne, Illinois* 60439

The study population is comprised of about 4000 persons (mostly males) who worked at a thorium processing plant from the mid 1930's until 1973. Mortality and causes of death (from death certificates) are being studied with internal comparisons (by job classification and length of employment) and external comparisons (using U.S. mortality rates specific for sex, age, time and cause). For morbidity studies, subgroup of 558 males (who worked for one year or longer in jobs probably involving highest exposure levels to thorium) has been selected, and questionnaires on medical and occupational history, respiratory symptoms and personal habits (smoking and alcohol consumption) have been sent to those not known to be dead. A random sample of 100 of these 558 men has been selected for a pilot study which involves measurement of radioactivity levels, and a medical examination (including pulmonary function tests). Interest in the health of thorium workers stems mainly from the potential importance of thorium as an energy source. Lung cancer and other lung diseases (e.g., pneumonoconiosis) are of particular interest in these studies, since the major hazard involved in the thorium extraction process is believed to be related to inhalation of airborne thorium and thorium daughter products.

ATLANTA CANCER SURVEILLANCE CENTER

M.A. Child, Emory University, School of Medicine, Dept. of Preventive Medicine & Community Health, *1364 Clifton Rd. N.E., Atlanta, Georgia* 30322

The Atlanta Registry is one of eleven funded and sponsored by the National Cancer Inst. of the United States. Each represents a unique set of persons with respect to climate, race, industrialization, lifestyles, and heritage. Atlanta represents a growing but not particularly industrialized city in the southeastern USA with a large black population and whose long-time resident white population is largely Anglo-Saxon. The study's overall objective is registration and follow-up of every case of cancer in the Atlanta Standard Metropolitan Statistical Area and a separate ten county rural area whose population is largely black. Patients are identified through hospital medical record departments, pathology laboratories, radiotherapy facilities, and death certificates. Collected by specially trained abstractors are demographic information, birthplace, census tract of residence, occupation, use of tobacco and alcohol, site and histological type of malignancy, diagnostic tests and procedures undertaken including surgery, radiotherapy, chemotherapy, and immunotherapy and the name of the physician following the patient. Patients are followed through re-admissions to hospitals, by information from the follow-up physician, and through death certificates. It is hoped that these data will identify persons at unusually high or low risk of cancer through various factors of environment and background. Because the registry is population-based, it will be able to produce incidence data and patterns of diagnostic and therapeutic care for the area. Survival information will be calculated and the effectiveness of different modes of therapy evaluated. Cooperation with special studies such as the

relationship of bladder cancer to the use of saccharin and other dietetic or occupational hazards, a study of black women with breast cancer, and the role of antigenic stimulation to multiple myeloma and chronic lymphocytic leukemia is planned.

PROSPECTIVE AND RETROSPECTIVE STUDY OF THE POSSIBLE RELATIONSHIP BETWEEN HERPESVIRUS TYPE II INFECTION AND GENITAL CANCER

Z.M. Naib, Grady Memorial Hospital, Dept. of Cytopathology, *80 Butler St. S.E., Atlanta, Georgia* 30303

Since 1964, more than 1,500 women were detected during routine cytological screening as having herpesvirus infection. These individuals are followed clinically and cytologically in a special herpes clinic: the incidence of cervical cancer was found to be approximately 10 times higher than in general populations cytologically screened. The main objectives of this study are to investigate the degree of this association and explain the nature of the association and related factors. The incidence of anaplasia was found to be higher in patients with primary herpesvirus type II infection.

THE JOHNS HOPKINS LUNG PROJECT FOR THE EARLY DETECTION, LOCALIZATION AND THERAPY OF LUNG CANCER

J.K. Frost, Johns Hopkins University, School of Medicine, Dept. of Pathology, *725 N. Wolfe St., Baltimore, Maryland* 21205 (01212)

This study began in 1969 when the Johns Hopkins Medical Institution was asked to (1) develop improved methods for the cytological detection of lung cancer, (2) develop improved methods for the localization of lung cancers that are not detectable by chest X-rays, and (3) test these screening techniques in a population sample. The procedures which evolved are now being employed in Phase II of The Johns Hopkins Lung Project and by the other two centers in the Early Lung Cancer Cooperative Study - The Memorial Sloan-Kettering Hospital for Cancer, and Mayo Foundation. The three collaborating centers are assisted in uniform data collection and analysis by the University of Cincinnati. The goal of the cooperative study is to determine the effect of early cytological or X-ray detection, followed by surgical therapy, on long-term survival in lung cancer, as measured by lung cancer mortality in the survey populations. The Johns Hopkins Lung Project has recruited 10,390 male smokers, aged 45 or over, from the Baltimore metropolitan community. Volunteers were randomized into (a) a group screened by annual chest X-ray, and (b) a group screened by sputum cytology in addition to their annual chest X-ray. All chest X-ray examinations include independent double reading. In addition, all sputum cytology screenees receive an annual examination of an aerosol-induced sputum specimen plus an examination of mailed morning sputum every four months. Subjects in whom cancer is detected may be admitted to the Johns Hopkins Hospital for localization and therapy. Curative resection is undertaken where possible, otherwise therapy includes chemotherapy and radiotherapy. All ten thousand subjects will be followed for at least five years to determine survivorship or cause of death.

MORTALITY AMONG DRY CLEANERS

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205

Workers in dry cleaning shops are exposed to such chemicals as tetrachloroethylene, trichloroethylene, petroleum solvents, and carbon tetrachloride, some of which are carcinogenic in animals. A cohort follow-up study of 10,000 members of a dry cleaning union between 1940-1977 is being conducted. Cause-specific mortality rates will be compared to expected rates from the general and local populations, and title and duration of membership will provide an indication of exposure gradients and latent periods.

MORTALITY AMONG US VETERINARIANS, 1950-1965

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205

Although transmission of oncogenic viruses from animals to humans has not been clearly demonstrated, this hypothesis continues to receive considerable support. Veterinarians represent a group with routine exposure to animals with viral diseases, as well as to chemicals and drugs. Using the obituary notices listed in the Journal of the American Veterinary Medical Association, the numbers of veterinarians dying from leukemia and Hodgkin's disease and cancers of the brain and skin between 1966 and 1977 were greater than expected, particularly among clinical practitioners (with expected numbers based on the US patterns). The distribution of the causes of death among 3,000 additional veterinarians dying during earlier years (1950-1965) is being analyzed to evaluate these intriguing patterns and to further identify high risks.

CANCER MORTALITY AMONG STRUCTURAL PEST CONTROL WORKERS

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205 (D-IARC-79-844)

The objective of the study is to determine whether persons applying various kinds of pesticides in non-agricultural settings experience unusual mortality patterns for cancer at specific sites that may be indicative of exposure to carcinogenic agents. The study group consists of approximately 5,000 persons who were employed by pest control firms in the state of Florida in 1965. The cohort will be followed for mortality to the present time and its site-specific cancer mortality rates will be compared to the general population of the area. Duration of employment and time since first employment in the trade will be considered in the analysis. Information on type of pest control work and general classes of pesticides used is also available.

COMPUTER-BASED, EXPOSURE-ORIENTED OCCUPATIONAL EXPOSURE CODE

P. Cole, University of Alabama in Birmingham, School of Community & Allied Health, Dept. of Public Health & Epidemiology, *Tidwell Hall BO06, University Station, Birmingham, Alabama* 35294

The purposes of this study are: 1) To develop a computer-based system whereby, given a job title and specification of industry, a list of possible occupational exposures to chemicals and other possible carcinogenic agents will be made available, 2) to evaluate the system as a tool for the study of occupational carcinogenesis using large data sets from a cancer registry.

CASE-CONTROL STUDY OF MALIGNANT GLIOMA

F. Hochberg, Massachusetts General Hospital, *32 Fruit St., Boston, Massachusetts* 02114

This is a case-control study of 230 newly diagnosed cases having malignant (grades II-IV) glioma. The controls (230) are the 'best friends' of the cases of the same sex and similar age. The controls are further specified by an algorithm. Information is gathered primarily by a mail questionnaire followed by a telephone contact. Interest is in exposure to radiation, childhood diseases and industrial compounds. To date 153 cases and 90 controls have been evaluated.

DIETHYLSTILBESTROL-ADENOSIS PROJECT - GENITAL TRACT ANOMALIES AND CANCER IN FEMALES EXPOSED IN UTERO (ABBREV)

S.J. Robboy, Massachusetts General Hospital, Dept. of Pathology, *32 Fruit St., Boston, Massachusetts* 02114

Young women exposed in utero to diethylstilbestrol are known to be at risk for the development of clear cell adenocarcinoma of the vagina and cervix. A large proportion of the exposed population is also known to have developed adenosis of the vagina, ectropion of the cervix, and variety of structural anomalies of the cervix and vagina, which have been described as ridges, rims, hoods or pseudopolyps. There is speculation that these women are also at a higher risk for the development of squamous cell dysplasia and carcinoma. The goal of this prospective study is to investigate the incidence and natural history of the above lesions. One thousand exposed women were identified through review of prenatal records, physician referrals and patients who presented themselves for examination. Controls for the cohort of subjects identified through review of prenatal records comprise a similar but non-exposed cohort. All subjects were examined initially in 1974-76 and will be re-examined at yearly intervals for a minimum of five years.

CORRELATION OF EPIDEMIOLOGICAL AND METABOLIC PARAMETERS - THE POSSIBLE ROLE OF VITAMIN A IN UTERINE CERVICAL DYSPLASIA

S.L. Romney, Yeshiva University, Bronx Campus, Albert Einstein School of Medicine, Dept. of Obstetrics & Gynecology, *1300 Morris Park Ave., Bronx, New York* 10461 (D-IARC-79-916)

In this study of carcinoma of the uterine cervix the primary focus is on the possible interrelationships of diet, with emphasis upon vitamin A, social environmental epidemiological factors, and the cellular changes which are detectable clinically by routine cytology and biopsy of the uterine cervix. The availability of the Papanicolaou test permits screening of large population groups and the finding of a positive or suspicious smear identifies 'women at risk'. Such women are being studied intensively in terms of (1) diet, with computer coding and scoring of nutrient values, (2) ethnic and socioeconomic background and (3) personal life-styles including educational performance as well as (4) measurements of specific blood and tissue retinol and retinoic binding proteins.

EPIDEMIOLOGY OF CANCER OF THE TESTIS IN UPSTATE NEW YORK

S. Graham, State University of New York, Buffalo Campus, School of Social Science & Admin., Dept. of Sociology/Social & Preventive Medicine, *3435 Main St., Buffalo, New York* 14214

The literature on cancer of the testis suggests a number of hypotheses dealing with possible relationships with cryptorchidism, occupational activity, clothing styles, sexual behavior, fertility, exposure to high temperatures, and the like. In our earlier demographic study of testis cancer it was found that the risk of testicular cancer was increased for persons who were in professional occupations, of several generations in this country, were rural or suburban dwellers, and had married early. We planned to interview all testis cancer cases from Upstate New York, beginning in autumn 1977. Names of cases will be made available to us as they are reported to the New York State Tumor Registry. To control for the fact that cancer of the testis appears to be a disease of high socioeconomic status, controls, matched on age (within 5 years), who reside in the neighborhoods of cases will be interviewed. It is anticipated that approximately 100 cases will be reported each year. Thus, in 3 or 4 years sufficient cases and neighborhood controls will be available for a definitive analysis. Data collection is under way. We have completed 76 case and 43 neighborhood control interviews.

RADIATION-ASSOCIATED THYROID CARCINOMA

K. Shimaoka, Roswell Park Memorial Inst., Dept. of Clinical Pharmacology & Therapeutics, *666 Elm St., Buffalo, New York* 14263 (01159)

A program has been instituted to screen annually by clinical and laboratory examinations those persons who have received radiation therapy to the head and neck areas for benign conditions. Those found to have goiter are further evaluated and treated by suppressive therapy with thyroid hormone. Those who respond are continued on long-term drug therapy, while those whose goiters increase in size are offered thyroidectomy. The natural history of radiation-associated benign and malignant thyroid diseases is being studied.

OCCUPATIONAL LUNG CANCER IN THE RUBBER INDUSTRY

D.A. Andjelkovich, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514

This study was prompted by conflicting findings in relation to occupational lung cancer in the industry. While an overall excess of lung cancer was found in Great Britain, an overall deficit was observed by us in the U.S. Accordingly, it was decided to investigate the relationship between mortality from this disease and specific occupational exposures. The main objective of this study is to identify, retrospectively, specific groups of workers who may experience an excess risk of mortality from lung cancer. In addition, the British report of an association between this disease and employment in areas where curing of green rubber products is performed is being evaluated and other published findings on a relationship between lung cancer and work in jobs involving compounding and mixing of raw rubber stocks is being examined. A case-control study design with over 100 cases and 400 controls is being used, matched on pertinent variables to eliminate confounding factors unique to occupational studies. The analysis involves examination of detailed employment records to determine whether cases were more likely to have worked in specific areas within the plant under study, which may now contain (or which may have contained in the past) respiratory system carcinogens. The design also includes an examination of certain non-occupational factors which may be responsible for the observed excess.

STOMACH CANCER AMONG RUBBER WORKERS - A CASE-CONTROL STUDY

S.B. Blum, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514

Whereas the incidence of stomach cancer has been steadily declining in the U.S. during the past few decades, our analyses have indicated that rubber workers remain at a considerably higher risk than the general population. Because of the diverse chemicals to which these workers are being exposed, many of which are known or suspected carcinogens, an analytical study is being conducted to determine whether this excess risk may be caused by industrial exposures to polycyclic hydrocarbons, nitrosamines, asbestos, or carbon black. All of these substances have been, or are being, used or generated by the industrial processes in the rubber industry.

FATAL LYMPHOMAS IN RUBBER WORKERS, A CASE-CONTROL STUDY

H.A. Tyroler, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514

Recent descriptive mortality analyses in five major US rubber companies have demonstrated a consistent excess of deaths among rubber workers from malignant neoplasms of the lymphatic and hematopoietic system (LHS). A case-control study has demonstrated an association between lymphatic leukemia and a history of having worked in jobs entailing solvent exposure. 87 persons, dying in period 1964-1973 with an LHS neoplasm diagnosed as lymphoma, have been individually matched with two pairs of controls, selected from non-cases within the source population from which the case derives. Complete work history information will be utilized for all study subjects. Analysis of case-control differences in work history will examine the association of leukemia types with solvent exposure and similarities and differences between exposure histories of fatal cases of lymphoma and leukemia.

PESTICIDE MANUFACTURER/FORMULATOR MORTALITY STUDY

B.W. Carnow, University of Illinois, Medical Center at Chicago, School of Public Health, Dept. of Occupational & Environmental Medicine, *Box 4348, Chicago, Illinois* 60680

This study is seeking to determine if selected groups of workers in the pesticide manufacturing/formulating industry experience excess cause-specific mortality. Although a number of epidemiological studies have been carried out to examine the relationships between chronic pesticide exposure and morbidity and mortality, most have not included sufficient population numbers, length of exposure and latency periods in the study design. A cohort of approximately 4,000 workers who were employed in the pesticide manufacturing/formulating industry for a minimum of 12 months prior to 1960 will be studied and their mortality experience will be compared to that of the general population for 60 causes of death. In addition, attention will be directed to various categories of malignant and non-malignant lesions specifically associated with exposure to organo-chlorine pesticides. A prospective cohort of workers in the pesticide industry will also be identified.

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF PCE WORKERS

D.P. Brown, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Perchloroethylene (PCE) is used extensively throughout the dry cleaning industry (100,000 workers). Tests for carcinogenicity in the Bioassay Program of the National Cancer Inst. show an increase in hepatocellular carcinomas in mice. To date, the effects on humans from long-term low level exposure to PCE are unknown, and the study will assess these by analysis of cause-specific mortality among an identified group of dry cleaning workers. A cause of death for each individual in the cohort will be determined retrospectively and the observed deaths will be compared to those expected based on a standard race-, sex- and age-specific population. Worker exposure to PCE in the dry cleaning industry will be characterized by industrial hygiene surveys. The Stanford Research Inst. (SRI) is conducting the mortality study under contract. Personnel records from four labor unions have been used to assemble a cohort of approximately 1,659 dry cleaning workers who were employed for at least one year prior to 1960 in a facility where the primary solvent was PCE. All of the demographic and work history coding has been completed and vital status follow-up through the Social Security Administration (SSA) has been accomplished. Once the SSA data is processed, it will be determined how much more vital status follow-up is necessary. Industrial hygiene surveys have been conducted in 30 dry cleaning facilities in San Francisco, Oakland, Detroit and Cincinnati. An additional 15-20 surveys are planned in New York City and Chicago, and a final report will be ready in early 1980.

3.1608,

COMPARISONS OF OCCURRENCE AND LEVELS OF DRINKING WATER CONSTITUENTS AMONG PAIRS OF HIGH AND LOW CANCER MORTALITY COUNTIES IN OHIO

D.G. Greathouse, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268

The basic study procedures and goals of this project are similar to those of the national study. As a result of at least two independent epidemiological studies attention has been focused on Ohio because of the high cancer mortality rates for counties supplied with drinking water from surface sources. Since Ohio counties represent wide contrasts in water sources, geology, industrialization, socioeconomic levels, and cancer mortality rates, it was judged that a study limited to Ohio would be worthwhile. The selection of study counties will be based on the county mortality data available from Ohio State University and the industrial data available from the Ohio Environmental Protection Agency and various publications.

3.1609,

MORTALITY, MEDICAL, AND INDUSTRIAL HYGIENE STUDIES OF CHLORINATED HYDROCARBONS

T.J. Meinhardt, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

In conjunction with industrial hygiene surveys under contract, NIOSH is determining the feasibility of conducting a mortality study of workers exposed to one or more of the chlorinated hydrocarbons, benzyl chloride, monochlorobenzene, methylene chloride and methylchloride. The posibility of doing such a study will in large part be determined by the existence of a sizable exposed worker population and appropriate personnel records. It has been found that it is not practical to study benzyl chloride because few workers are or have been exposed and also because adequate records on past workers are not available. A hygiene study has been conducted in a cross-section of the industry to document current exposure patterns to this chemical. The feasibility of doing epidemiological studies on workers exposed to the other three chemicals is currently being determined.

MORTALITY OF WORKERS IN THE NORTHWEST PAPER, PULP AND PLYWOOD INDUSTRY

C.F. Robinson, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Harzard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

In order to follow up an indication of excess cancer among workers in the wood processing industries in state and national mortality statistics, a retrospective cohort mortality study of workers in the Northwest paper, plywood and pulp industries will be conducted. Recent mortality studies conducted by Dr. S. Milham, Jr. show an excess of lymphatic and hematopoietic cancers in wood processing industry employees. Data from a NIOSH contract, 'Occupational Mortality in Washington State, 1950-71', suggest that persons working in the plywood, paper and pulp industries may be at particular risk. The present project aims to substantiate and refine the earlier occupational mortality findings. An effort will be made to localize any excess mortality within selected plants and to indentify agents and processes associated with this. General historical environmental descriptions for each plant will be developed. In-depth industrial hygiene surveys may be conducted if any excess mortality is observed. Nine plants were selected for study, including four plywood mills and five pulp and paper mills. Data on the study population have been collected, coded, and keypunched. After the data are edited and follow-up is completed, NIOSH will begin analyses of the mortality patterns of the study population.

3.1613,

MORTALITY, REPRODUCTIVE, AND INDUSTRIAL HYGIENE STUDIES OF CARBON DISULPHIDE WORKERS

S.G. Selevan, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Carbon disulphide is used in a variety of industries; it is used in the xanthenation of cellulose to produce viscose rayon and cellophane and as a solvent for sulphur chloride in vulcanizing rubber. Additional uses are as a solvent for rubber cement, phosphorus, fats, oils, resins, and waxes, as an insecticide and also in the manufacture of optical glass. The toxicity of carbon disulphide has been recognized for many years and it has been generally associated with central nervous system effects, such as loss of memory, excessive irritability, vertigo, melancholia and, in severe cases, dementia. More recent studies indicate an increased mortality and morbidity from cardiovascular diseases and effects on the reproductive systems of both men and women. A study of this agent conducted by the National Institute for Occupational Safety and Health has the following phases: (1) A mortality study under contract; (2) a study of mutagenesis by administering reproductive history questionnaires to wives of workers; (3) a cross-sectional study to investigate the adverse health effects in workers exposed to carbon disulphide, and (4) an industrial hygiene study to determine present carbon disulphide exposure levels and estimate working lifetime exposures.

3.1614,

MORTALITY, MEDICAL AND INDUSTRIAL HYGIENE STUDIES OF WORKERS EXPOSED TO SYNTHETIC ESTROGENS

S.G. Selevan, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Synthetic estrogens are a group of synthetic hormones having serious potential effects on exposed workers. Women taking oral contraceptives have an increased risk of thromboembolism, cerebral vascular disease, and myocardial infarction. A study by the National Institute for Occupational Safety and Health (NIOSH) carried out in an oral contraceptive plant indicated that problems are occurring in both males (gynecomastia) and females (menstrual changes). Also, it has been noted that estrogens may be carcinogenic. A cross-sectional medical/environmental study is proposed to investigate health problems resulting from exposure to synthetic estrogens and to attempt to determine a safe level of exposure to these agents. A mortality study of workers occupationally exposed to oral contraceptives will be performed to determine if an excess number of carcinoma deaths have occurred in exposed workers.

A STUDY OF CANCER AND THE PUBLIC DRINKING WATER SUPPLIES IN MISSOURI

C. Marienfeld, University of Missouri, Columbia Campus, School of Medicine, Dept. of Community Medicine, *M228 Medical Sciences, Columbia, Missouri* 65201

This project involves setting up a data base of mortality, morbidity, and environmental information for rural postal routes grouped into rural water supply areas. This technique permits comparison of cancer rates for water supply areas which differ considerably in terms of water quality, industrial exposures, geology, and socioeconomic characteristics. County units which are often used may not coincide with water utility service areas. This project should permit an evaluation of the health and environmental (primarily drinking water) consequences of existing or newly established industrial and/or mining operations within rural areas.

RETROSPECTIVE STUDY OF CANCER IN BLACK AND WHITE POPULATIONS

S. Albert, Michigan Cancer Foundation, Dept. of Biometry & Medical Sociology, *110 E. Warren Ave., Detroit, Michigan* 48201

It is recognized that certain cancers differ in white and black populations with respect to extent of disease at diagnosis and survival. The purpose of the present study is to characterize the 10 most frequent

cancers in the black and white populations. The study is concerned with incidence, histological types, organ distribution (where applicable), extent of the disease at diagnosis, treatment and survival. These characteristics are being studied over a period of time, not less than years, to determine whether any changes have occurred. This study is also designed to determine whether Detroit is similar to other areas or whether there are regional differences.

GASTRIC CANCER IN SAN MARINO

C.E. Jackson, Henry Ford Hospital, Dept. of Medicine, *2799 W. Grand Blvd., Detroit, Michigan* 48202

The purpose of this project is to define the genetic and environmental factors causing the high frequency of gastric cancer observed in San Marino. Initial studies have revealed a higher percentage of patients with first degree relatives affected than in the controls. Screening of segments of the population by gastroscopy is being undertaken in attempts to detect the neoplasms early. The project is a cooperative one between physicians in San Marino and in Detroit, Michigan, USA which has a large San Marinese population. Further interim results have been published in Cancer, 1980. Salmonella mutagenicity testing of urine of patients and relatives as well as that of controls and ingested material is planned.

THE EPIDEMIOLOGY OF MULTIPLE MYELOMA

S. Grufferman, Duke University, School of Medicine, Dept. of Pediatrics, *Box 3711, Durham, North Carolina* 27710

The major objective of this case-control study is to learn more about the epidemiology of multiple myeloma. Surprisingly little is known about the epidemiology of this disease, available information is dated, and there are few aetiological hypotheses. The study will have two major components: a medical record review of 450 multiple myeloma cases and an interview study of an additional 150 patients, both components involving matched hospital controls. In addition to examining for associations with available demographic variables, associations between multiple myeloma and socioeconomic class, occupation, environmental exposures, diet, and diseases causing 'immune stimulation' will be evaluated. Particular attention will be paid to evaluation of the association between socioeconomic class and multiple myeloma. Paradoxically, multiple myeloma is reported as being positively associated with high socioeconomic class whereas incidence rates are twice as high in blacks as in whites.

CLINICAL CANCER GENETICS

L.C. Strong, University of Texas, University of Texas System Cancer Center, Dept. of Pediatrics/Biology, *6723 Bertner Ave., Houston, Texas* 77030

The objectives of this study are to identify unusual familial aggregations of childhood cancers, associations of childhood cancer and congenital anomalies, or the occurrence of rare tumours in childhood for further aetiological study. Patients are referred from clinical departments. All cancers or other disorders in families under study are documented by medical records and/or vital statistics. Documented familial cases are compared with nonfamilial cancer cases with respect to age at onset, anatomical site, multiplicity of cancers, congenital and chromosomal abnormalities or other predisposing conditions. Within affected families, various clinical and genetic markers are being evaluated.

GENETIC CONSEQUENCES OF CHILDHOOD CANCER

L.C. Strong, University of Texas, University of Texas System Cancer Center, M.D. Anderson Hospital & Tumor Inst., Dept. of Pediatrics/Biology, *6723 Bertner Ave., c/o Texas Medical Ctr., Houston, Texas* 77030

The objective of this study is to identify genetic effects of cancer and therapy, including both the primary factors predisposing to cancer which may lead to subsequent tumors in the patient or heritable tumors in offspring, and treatment-induced mutations which may lead to subsequent tumors or heritable disease in the offspring of patients who have had childhood cancers. A registry of long-term survivors of childhood cancer and their offspring is being established, including data concerning congenital anomalies, predisposing conditions, family history, primary cancer treatment, and other medical or social history. Multiple factorial analysis of risk factors of second tumors and of genetic disease in the offspring will be undertaken.

WISCONSIN CANCER REPORTING SYSTEM - CANCER SURVEILLANCE AND RESEARCH

M.A. Woodbury, State Bureau of Prevention, Section of Epidemiological Surveillance & Assessment, *P.O. Box 309, Madison, Wisconsin* 53701

The overall objective of the epidemiological study section of the Wisconsin Cancer Reporting System is the identification of high risk population groups, environmental factors and potential carcinogenic agents. This is a long-range plan currently directed toward developing the tools necessary for providing a mechanism for identifying cancer morbidity and mortality events or patterns significantly deviating from past trends. A computer program will be written to indicate such occurrences. Specific epidemiological studies will determine the factors involved, should the unusual event or pattern not be the result of changes in reporting habits. A computer program will also be developed to correlate an ongoing basis on various environmental conditions with cancer morbidity and mortality. (For example, a study of the degree of correlation of cancer mortality by distance from a taconite mine with measurements of asbestos in air, water and soil by distance from the mine.) It is anticipated that such computerized surveillance will substantially increase the ability to recognize changes early and to set in action the analytical epidemiological studies required.

PHYSIOLOGICAL CORRELATES OF LEUKEMIA

D.E. Dix, University of Hartford, School of Arts & Sciences, Dept. of Biology, *200 Bloomfield Ave., West Hartford, Connecticut* 06117

All tumors classified by the Connecticut Tumor Registry in 1968-1972 (Cancer Incidence in Five Continents III, IARC, 1976), with the exception of chorionepithelioma, were divided into two classes. Class tumors, representing 76 of the 83 tumor types classified by the Registry, exhibit similar patterns of incidence as a function of age with peak incidence occurring at ages greater than 50. It is suggested (J. Theoret. Biol, in press) that the incidence of all class I tumors is determined by mutations which become more probable with advancing age. Evidence suggests that the incidence of cancer declines at ages greater than 80 and it is known that cells lose the ability to divide in old age and we suggest that neoplastic mutations occurring in such cells would not produce a tumor. Class II tumors (acute lymphocytic leukemia, Hodgkin's disease, and tumors of bone and testis) exhibit maximum incidence at ages less than 35. In analogy to the class I tumors, we propose that neoplastic mutations become most probable in tissue of origin of class II tumors at the ages of maximum incidence. We propose to explain the decline in incidence of class II tumors at later ages as premature senescence; the tissues of origin lose the ability to carry out cell division. We are currently seeking experimental support for this theory. Since acute lymphocytic leukemia belongs to class II and the other leukemias belong to class I, we are focussing our efforts on developmental differences between lymphocytes and the other hematopoietic cells. We hope to correlate our findings with the neoplastic process in bone, testis, and Hodgkin's disease.

EXPOSURE TO HALOGENATED ORGANIC CHEMICALS FROM DRINKING WATER

C.D. Pfaffenberger, University of Miami, School of Medicine, Dept. of Epidemiology, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152

Methods for determining trihalomethanes in human blood and adipose tissue have been developed. Animal models have been used to determine the sensitivity of the technique in assessing exposure to chloroform, carbon tetrachloride, trichloroethylene, bromodichloromethane and p-dichlorobenzene. A body burden survey of persons exposed to various levels of trihalomethanes in their drinking water is in progress. Persons living in the environs of Miami, Florida, having different levels of trihalomethanes in their drinking water are participants in the study. Each participant is interviewed and a blood sample drawn for trihalomethane level determination. So far levels of chloroform have been observed in all participants in the range of 2-400 parts per billion. No bromomethanes have been detected in serum.

CONNECTICUT TUMOR REGISTRY - FORTY YEARS OF CANCER INCIDENCE

J.F. Heston, Connecticut Cancer Epidemiology Unit, *30 College St., New Haven, Connecticut* 06510

A compilation of the incidence and mortality data of the Connecticut Tumor Registry (CTR), 1935-1974, has been prepared to make the data generally available. Because of the uniquely long history of the population-based CTR, its data are of particular value in the study of secular trends. The introduction will present information on factors in the Registry operation and its development which may have influenced registration. For 60 major cancer sites or types and 14 important subsites, as classified in the 'International Classification of Diseases for Oncology, 1976' (ICD-O) (WHO), tables of frequencies and rates of incidence by sex, 5-year age groups, and 5-year time periods are presented. For all sites of greatest frequency, tables have been included for annual frequency, percentages of cases histologically confirmed, cases registered first at autopsy, and cases registered from death certificate only. For other sites, the latter tables will be available upon request. Each table is presented by ICD-O title and number, the comparability of rubric inclusions over the registration period having been checked. Summary tables of age-adjusted rates (US 1950 and 1970) by sex and quinqennia for the major sites are presented. This report will be an in-house publication in 1980, and it is anticipated that it will be available on tape.

COLORECTAL CANCER - FACTORS RELATED TO SURVIVAL

T.R. Holford, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510

Cancer of the colon and rectum have the second highest cancer incidence among women and the third highest among men in the United States, the median survival time being about 2.2 yr and 2.0 yr respectively. This project will investigate prognostic factors for survival from colorectal carcinoma using cases on file in the Connecticut Tumor Registry, which is a member of the Cancer Surveillance, Epidemiology and End Results (SEER) Group. Statistical methodology will be developed so that survival analysis with covariates can be done for cancer registry data. The analysis will simultaneously consider, using a regression-like approach, the effect of several factors on survival so that the interrelationships can be

investigated. The variables of interest include age, race, and sex, treatment, and extent of disease. In addition, information on socio-economic status, environmental factors, and associated lesions will be investigated to determine their effect on survival.

ESTROGEN AND GENITAL CANCERS - AN EPIDEMIOLOGICAL STUDY
J.L. Kelsey, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510
This is a case-control study of women in the age range 45-74 years which seeks to determine if use of oestrogen replacement therapy during and following menopause or use of oral contraceptives during the reproductive years alters the risks for cancer of the breast, ovary, or corpus uteri. Particular attention is being paid to specific histological types and to the stage of the disease. Statistical analysis will include consideration of such variables as total length of use, date when first used, and specific compounds used; the possibility of different risks in subgroups of women will also be considered.

RADIATION AS A CAUSE OF BREAST CANCER WITH PARTICULAR REFERENCE TO ACNE TREATED BY RADIATION
N. Simon, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Radiation Research, *1 Gustave L. Levy Pl., New York, New York* 10029
Women who had previous radiotherapy for acne should be added to the radiation exposures previously known to cause breast cancer - young women fluoroscoped for tuberculosis, survivors of atomic bomb explosions and post-partum irradiated mastitis. 43 patients with cancer of the breast who have had previous irradiation for acne have been identified in our department. The number of women who have had radiation for acne is now being investigated, to attempt to determine the incidence of cancer of the breast in such women. This survey of a population of women has been started as a feasibility study of 1,000 women in New York. The survey will concentrate on radiation histories of patients with cancer of the breast.

3.1631,
COLON CARCINOMA, DIET AND THE MICROFLORA
M.H. Floch, Norwalk Hospital, Gastrointestinal & Nutrition Laboratory, *24 Stevens St., Norwalk, Connecticut* 06856
Populations with a low incidence of cancer of the colon (African, Indian and Japanese) consume a low fat, high fiber diet and exhibit differences in their fecal microflora and fecal acid and neutral steroids excretion when compared to populations with a high incidence of colon cancer. This study is examining differences between these factors in patients with colon cancer, patients with cancer other than gastrointestinal, and control subjects, all from a population with a high incidence of colon cancer. The comparison of dietary factors obtained through dietary histories indicates no significant differences between the three groups. The predominant fecal flora of the colon cancer group shows an increase in aerobic bacteria compared with controls. No differences are observed with regard to species of the organisms. The comparison of the non-gastrointestinal cancer patients with controls also shows significant variations (decrease in total anaerobes and Eubacterium species). Total bile acid and neutral steroids excretion is not significantly different in the three groups. The colon cancer group does, however, excrete less lithocholic, coprostanol, and coprostanone compared to the control group. Final evaluation of follow-up medical data is presently being undertaken.

3.1632,
AN EPIDEMIOLOGICAL STUDY OF THE LONG-TERM EFFECTS OF GRISEOFULVIN IN MAN
E. Mahboubi, University of Nebraska, Medical Center, School of Medicine, Dept. of Epidemiology, *42nd & Dewey Aves., Omaha, Nebraska* 68105
This study examines epidemiologically the anti-fungal drug griseofulvin. The study has been initiated as a result of recent findings by the Eppley Cancer Institute indicating that griseofulvin induces thryoid tumors in rats. The drug had previously been found to induce liver neoplasms in mice. Based upon available information the objectives are: (1) To identify, locate and establish groups of persons throughout the United States, and possibly some Western European countries who have, in the past 18 years or so, used griseofulvin for treatment of various skin diseases and other illnesses, and (2) to evaluate the possible carcinogenicity and teratogenicity of the drug.

CASE-CONTROL STUDY OF WATER QUALITY AND CARCINOGENESIS IN PENNSYLVANIA
A. Bahn, University of Pennsylvania, School of Medicine, Dept. of Community Medicine, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174
This is a case-control retrospective study of colon cancer in four counties - Philadelphia, Delaware, Chester, and Bucks - of Pennsylvania. Decedent cases (colon cancer) and controls (deaths due to causes other than cancer) will be drawn from the state mortality records and the next-of-kin listed on the death certificates will be interviewed. Live cases will be selected from hospital records and controls will be randomly selected from the counties. For each case and control information will be obtained concerning residence, occupation, and medical histories, smoking habits, dietary patterns and medicine usage. Detailed chacterization of water sources, treatment methods and chemicals will be obtained. Relationship(s) between routine water analyses and the detailed organic analyses will be investigated for use in historical extrapolation of specific organic contaminant levels in the water. A further major goal of the project is to investigate and compare alternative case-control study methods. Effectiveness of using next-of-kin of decedents for determining relevant exposure will be compared with the use of live cases. Effect of time between death and interview in reliability and usefulness of data will be evaluated. The methodological information obtained will be useful in future investigations of the role of water constituents in the development of chronic diseases.

3.1635,
WATER SOURCES AND CHARACTERISTICS AND RISK OF MALIGNANCIES OF SELECTED SITES IN SELECTED LOUISIANA PARISHES
M.S. Gottlieb, Tulane University of Louisiana, School of Medicine, Dept. of Biostatistics & Epidemiology, *1430 Tulane Ave., New Orleans, Louisiana* 70112
In order to determine whether certain drinking water sources predispose individuals to cancer, deaths from cancer of selected sites will be matched to control deaths from non-cancer (non-related causes) within groups of selected parishes with similar characteristics except having differing water sources (river and ground). Matching will be for age, sex, race, and year of death. Cases and controls will be characterized by place of birth, ancestry (Acadian or otherwise), water source and characteristics, occupation and industry, and distance from industry. Length of time on water source for individuals will be determined from residence data, characteristics of the water during the last ten years of life, as well as distance of the residence from local industries characterized by type, size and length of exposure time. These factors will be compared for cancer deaths and non-cancer deaths to determine the contribution of single and multiple variables to the likelihood of dying from cancer. An incidence study will follow for selected sites and parishes where the mortality risk is high. This will be followed by a case/control interview study, including carcinogen screening for selected parishes at high risk for selected sites.

EFFECT OF EARLY DETECTION AND TREATMENT ON SURVIVAL FROM LUNG CANCER

M.R. Melamed, Memorial Sloan Kettering Cancer Center, Dept. of Pathology, *1275 York Ave., New York, New York* 10021

This study was undertaken to determine whether systematic, periodic examinations of sputum cytology, supplementing chest x-ray, could lead to earlier detection of lung cancer in a high risk group and to a reduction in death rate. The population chosen for study is volunteer men, in the New York metropolitan area, over the age of 45 years, who smoke more than one pack of cigarettes daily. A total of 11,000 men will be recruited into the study and all will have posteroanterior and lateral chest x-rays annually; approximately half will also have sputum cytology examinations at four-month intervals. The study is expected to require 5-10 years, and is being conducted in cooperation with the Mayo Clinic Foundation and Johns Hopkins University where additional populations are being surveyed in the same fashion.

3.1638,

EPIDEMIOLOGY OF MINIMAL BREAST CANCER IN INITIALLY ASYMPTOMATIC WOMEN

B.S. Pasternack, New York University, School of Medicine, Dept. of Environmental Medicine, *100 Washington Sq. E., New York, New York* 10003

The goal of this study is to determine, by means of risk factor analysis, whether minimal breast cancer in initially asymptomatic women is essentially different from clinical breast cancer or whether it is an early manifestation of the same disease. Demographic and medical data recorded at the Guttman Breast Diagnostic Institute, which has been offering free breast examinations to women living in New York City since 1968, will be utilized. The study group will consist of an estimated 1,000 cases detected up to the end of 1979 and a random selection of approximately 2,700 controls. Two independent histopathological diagnoses will be obtained. Cases will be compared according to three tumor criteria: invasiveness (minimal vs. clinical), aggressiveness (prevalent vs. incident), and histological type. Controls will be used to confirm relative risk estimates for study factors. Comparison of all cases to controls should result in estimates of relative risk within the range found at other screening centers, whereas the comparison of clinical cases to controls should provide estimates within the same order of magnitude as registry data.

MORTALITY STUDY OF OCCUPATIONAL EXPOSURE TO HALO ETHERS

B.S. Pasternack, New York University, School of Medicine, Dept. of Environmental Medicine, *100 Washington Sq. E., New York, New York* 10003

Chloromethyl-methyl ether (CMME) and his-chloromethyl ether, an impurity (2-8%) in commercial CMME, are alkylating agents having diverse use in the chemical industry. Animal studies have demonstrated that both compounds are potent lung carcinogens. A retrospective cohort study of occupational exposure to CMME was initiated in 1972 to evaluate the human carcinogenicity of these compounds. The initial survey showed a clear excess of respiratory cancer among the CMME-exposed workers, and a strong exposure-response relationship. Other findings among the exposed workers were a considerable number of respiratory cancers at early ages (before age 45), an excess among both smokers and non-smokers, and an inverse relationship between dose and respiratory cancer latency. Particularly because of the latter finding, another mortality survey is underway to better characterize the risk for those with lower exposure levels. The survey will include all seven major CMME producer and user firms in the USA for the time period 1948-1979. An estimated 2,000 CMME-exposed workers and 3,500 unexposed workers will be available for study.

INCIDENCE OF SKIN AND LIP CANCER IN USSR, ROLE OF SOLAR ULTRAVIOLET RADIATION IN AETIOLOGY OF SKIN CANCER, MELANOMA AND LIP TUMORS

L.N. Guslitser, Academy of Sciences of the Ukrainian SSR, R. Kavetsky Inst. for Oncology Problems, General Mechanisms of Carcinogenesis, *Vasilkovskaya St. 45, Kiev 252127, Ukrainian S S R, Union of Soviet Soc. Republics* (D-IARC-79-1078)

The main aim of this study is the establishment of incidence rates for skin and lip cancer in different regions and selected ethnic groups of the USSR. To determine the role of solar ultraviolet radiation in the causation of skin and lip cancer, correlation analysis of different climatic factors and the incidence of these cancers in the various republics and regions of the USSR will be undertaken. It is proposed to complete special questionnaires for patients with skin and lip cancer and appropriate controls. Using cancer incidence data for the most frequent sites, it is proposed to study time trends for the periods 1960-1975 for Ukrainian SSR and selected regions thereof.

A STUDY OF CANCER FOLLOWING MULTIPLE FLUOROSCOPIES

A.B. Miller, University of Toronto, *Medical Sciences Bldg., Toronto, Ontario, Canada* M5S 1A8

This cohort study is designed to evaluate the carcinogenic risk from ionizing radiation in the dose range 0 to 100 rad and for the major cancer sites to establish if there is a possible dose-response relationship. The study population consists of patients first admitted to Canadian tuberculosis sanitaria between the years 1930 and 1952. A substantial proportion (40 to 50%) were fluoroscoped regularly in conjunction with artificicl pneumothorax treatment and consequently accumulated a substantial radiation dose consisting of many exposures over a period of time. Information on the admission and treatment records of these patients has been extracted from the original sanitaria files. The data, consisting of approximately 130,000 records, have been keypunched. Two computerized record linkage steps using the identifying information present on the records are currently being undertaken. The first is to internally link the records so that admissions referring to the same individual will be brought together to form a composite record. Th3 second step is to link these composite records to the mortality data base maintained by Statistics Canada for the years 1950 through 1974, in order to ascertain the mortality experience of the cohort. A dosimetry study has been completed and published (Health Physics 35(2):259-70, 1978) which determines the dose experienced by various body organs exposed to radiation from fluoroscopies. The dosimetry information will be applied to the individual patient records in order to estimate the radiation dose received by each patient. The analysis will consist of estimation of relative risks with respect to mortality for different cancer sites as a function of dose calculated relative to those members of the study population who are not fluoroscoped.

A STUDY OF LONG-TERM CANCER SURVIVORS

B. Modan, Chaim Sheba Medical Center, Dept. of Clinical Epidemiology, *Bitan 27, Tel Hashomer, Ramat Gan, Israel*

The main objectives of this study are to determine the incidence of long-term survivors among patients with selected malignant disorders in Israel; to attempt to establish whether long-term survivorship is related to such factors as ethnic origin, disease type, and/or early detection; and to attempt to define early predictors that would permit prospective identification of patients with long-term survival. The study will be based on patients surviving ten years or more, with selected malignant disorders, diagnosed in any general hospital in Israel during the period of 1960-1964. Three controls surviving less than two years will be chosen for each case. The first control will be random, the second matched for age, and the third matched for age and sex. The crucial issue is whether we can, at an earlier stage, predict who will be the patients who are likely to become long-term survivors. The possible identification of these patients is of utmost clinical importance, since these patients should be approached differently, with either more or less vigorous therapy.

SPATIAL AND TEMPORAL VARIATIONS IN FOUR COMMON CANCERS IN BLACK GOLD MINERS FROM SOUTHERN AFRICA

J.S. Harington, South African Inst. for Medical Research, *Hospital St., P.O. Box 1038, Johannesburg 2000, Transvaal, South Africa*

In previous work on the gold miners, the pattern of cancer in Black gold miners over the eight-year period 1964-71, constituting 2,926,461 man-years of employment, was studied. Of the 1,344 cancers found, primary liver cancer accounted for 52.8%, oesophageal cancer 12.1%, cancer of the respiratory system 5.4%, and cancer of the bladder 4.8%. Analysis of the spatial distribution of these four cancers, both on subcontinental and local scale, showed distinct gradients of significantly higher and lower incidence than expected. In the case of primary liver cancer in Mozambique and oesophageal cancer in Transkei, the spatial distribution reflects closely that found in the general resident population of each territory. The crude incidence rate of primary liver cancer in gold miners from Mozambique dropped sharply over the period of the survey. The survey continues.

CANCER EDUCATION AND SCREENING PROGRAM FOR TEXTILE AND FURNITURE INDUSTURIES

S. Heyden, Duke University, School of Medicine, Dept. of Community & Family Medicine, *Box 3711, Durham, North Carolina* 27710

The first project, the Cannon Mills Cancer Education and Screening Program in Kannapolis and Concord, North Carolina was completed in 1977, while other industries are presently participating in similar programs. One of the objectives is to detect specific industrial cancer risks in the textile and furniture industries (e.g., bladder cancer, lung cancer, nose cancer). So far, none of these cancers have shown any appreciable accummulation, i.e., the risk of developing these cancer types appears no higher in the two industries compared to the general population of North Carolina. A description of the first completed project follows: cancer education and screening program was conducted among 19,000 Cannon Mills workers in North Carolina. Lectures were presented on company time for all employees within each of the three 8-hour shifts. This group education contained information on six cancer types felt to be amenable to screening and in which early detection can be expected to increase survival: breast, cervix, colon, bladder, prostate and oral cavity. After the completion of lectures employees were offered a screening examination. Thirteen thousand employees accepted and were screened between 2/1/76 and 1/31/78. The cost of screening was ten dollars per person.

Thirty-two asymptomatic patients who participated in the screening were discovered to have cancer. The compliance among those who had positive findings, and who were advised to see their M.D.'s was 90% among female and 81% among male employees.

The program received unanimous approval of the Carbarrus County Medical Society, which has recommended it for other counties. The state of North Carolina has also adoptedthis program as a pilot program among 10,000 state employees, with the assistance of Blue Cross/Blue Shield.

CHILDHOOD CANCER

M.A. Rahim, Dacca Medical College Hospital, Dept. of Radiotherapy & Chemotherapy, *49 E. Azimpur Govt. Estate, Dacca 5, Bangladesh*

Factors affecting a child suffering from malignant neoplasms will be studied under the auspices of the Bangladesh Cancer Epidemiology Research Program (BCERP). The aim of the study is (1) to determine the occurrence and age, sex and religious distribution of childhood neoplasms (primarily lymphomas and leukemias); (2) to study the geographical distribution of these diseases in different districts; (3) to calculate mortality in the light of cases registered by the BCERP and (4) to plot an area map for the study of time-space clusters. Radiotherapy, hematology and histopathology units of the radiotherapy centers in Bangladesh will participate and BCERP tumor registry forms will be utilized for recording. Subsequent compilation and analysis will be done centrally at BCERP.

Description provided by IARC and DKFZ with ICRDB/NCI support.

EPIDEMIOLOGY OF LUNG CANCER

M.A. Rahim, Dacca Medical College Hospital, Dept. of Radiotherapy & Chemotherapy, *49 E. Azimpur Govt. Estate, Dacca 5, Bangladesh*

Recent publications in the Bangladesh Medical Research Council Bulletin and Bangladesh Cancer Reports (Rahim, 1975; Rahim et al, 1977; Rahim et al, 1978) have shown that the highest cancer mortality rate for males is that for lung cancer. In this study the relationship between lung cancer and smoking in Bangladesh nationals will be examined. Patients will be interviewed to obtain information on the variety of tobacco smoked (Bidi, Hubblo-Bubble, country-made, processed, filter-tipped, etc.), the amount smoked and degree of inhalation. Questions have been designed to collect these data from the radiotherapy units in Bangladesh. All records will be collected by the Bangladesh Cancer Epidemiology Research Program for analysis.

Description provided by IARC and DKFZ with ICRDB/NCI support.

BANGLADESH CANCER EPIDEMIOLOGY RESEARCH PROGRAM

M.A. Rahim, Dacca Medical College Hospital, Dept. of Radiotherapy & Chemotherapy, *49 E. Azimpur Govt. Estate, Dacca 5, Bangladesh*

The aim is to examine the relative frequency of all cancers. Hospitals where radiotherapy facilities are available have been selected for the study. Participation of other hospitals which lack a radiotherapy center is voluntary. Consultants attached to participating hospitals are co-investigators. After interview and examination a clinical report is prepared, one for each patient, in the ad hoc tumor registry of BCERP. The records are collected centrally for compilation and statistical analysis. Three articles have been published and results show that cancer of the larynx, lung and oropharynx is frequent in males, and cancer of the cervix, breast and oral cavity frequent in females.

HISTORICAL REVIEW OF MALIGNANT MELANOMA IN ALBERTA 1967-1976

J.M. Birdsell, Southern Alberta Cancer Centre, Dept. of Epidemiology, *2104 2nd St. S.W., Calgary, Alberta, Canada* T2S 1S5

Records of all patients diagnosed as having melanoma of skin or eye during the past ten years were identified from the Alberta Cancer Registry. These files were reviewed and information collected on sex, age, residence history, method of diagnosis, site, pathological features, stage at diagnosis, duration of stages, sites of metastases, treatment and survival. Analysis of data on 99 ocular melanoma patients showed that ocular sites constituted 16% of all melanomas for that period, and 70% of ocular malignancies were melanomas. Female patients had a much higher incidence of the more malignant mixed

cell type tumors than males, while the converse was true of the less malignant spindle cell melanomas. Within each cell type, females survived significantly longer than males. The actuarial five year survival rate of males and females combined was 62%. Metastases occurred in 29 of the 99 patients, with liver being the sole or concomitant initial site of metastases in 22 of these cases. There was no improvement in survival rates over the ten-year period. Analysis of data of skin melanoma patients is underway and will provide information on the incidence, treatment given, recurrence and survival rates and the correlation of various factors with prognosis.

EPIDEMIOLOGICAL ASPECTS OF CARCINOMA OF THE CERVIX

C. Giordano, Faculdade de Ciencias Medicas da Santa Casa de Sao Paulo, Dtpo. de Obstetricia e Ginecologia, *Rua Dr. Cesario Mota Junior, N 112, Sao Paulo 01221, Brazil*

The low income female population constitutes the major portion of those attending the clinics of general hospitals in Brazil for screening for cancer of the uterine cervix. This study aims to characterize, in this low revenue population, those that are at 'high risk' for cervical cancer utilizing 18 variables obtained from complete gyr.ecological examination, cervical cytology, colposcopy and biopsy. The preliminary work of collection of the data has been undertaken over the past two years. The data will now be processed by discriminative analysis to determine which of the variables examined could be a contributing factor to cervical cancer.

EPIDEMIOLIGY OF CANCER IN THE NATIVE INDIAN POPULATION OF ALBERTA

L.M. Laing, University of Alberta, Dept. of Community Medicine, *Edmonton, Alberta, Canada* T6G 2E1

Native Indian populations are in cultural transition. The movement away from aboriginal patterns of adaptation is accompanied by changes in lifestyle and exposure to factors which may increase the risk of cancer. Risk factors include changes in reproductive patterns, a diet based on processed foods, occupational exposure to toxic substances, and increasing use of alcohol, tobacco, and drugs. Published information on cancer incidence and morality among native populations is relatively scant. The pattern of incidence of cancers among native Indian and Eskimo popualtions is different from that among other residents of North America. Malignant disease may once have been rare in native Indian and Eskimo populations. Cancers of the gallbladder and nasopharynx are significantly more frequent among native Indians. Cancers of the cervix and lung appear to have increased in relative prevalence. The Government of Canada maintains records of registered Indians through the Departments of Indian and Northern Affairs and Health and Welfare. There are approximately 32,000 registered Indians who are residents of Alberta. Lists of registered Indians will be matched with files of the Alberta Cancer Registry and with death certificates. An historical prospective study of cancer incidence and mortality among native Indians will be undertaken. It is estimated that for the study period 1974-78 there will be about 100 cancer deaths.

CANCER INCIDENCE ATLAS

R. Dewar, Alberta Provincial Cancer Hospitals Board, Dept. of Epidemiology, *11560 University Ave., Edmonton, Alberta, Canada* T6G 1Z2

This study is concerned with the observed geographical variation in the incidence of all malignant diseases in Alberta. The objective of the study is to provide a tool to researchers which will allow them to test various environmental, occupational and genetic hypotheses, provide grounds for developing new hypotheses regarding cancer etiology, and serve as a planning tool for administrators. The methods involve an analysis of county age-sex adjusted incidence rates, calculated from Alberta registry data for the years 1961-1977. In all, some 68,000 malignancies are to be studied. A series of maps will be published in monograph form, showing geographical variation by site.

CARCINOMA IN SITU AND DYSPLASIA OF UTERINE CERVIX IN RELATION TO AGE, PARITY AND BEGINNING OF SEXUUAL RELATIONS

C.A. Masi, Inst. Nacional Regional de Oncologia, Gynaecology Section, *Bv. Zavalla 3399, C.C. No. 366, 3000 Santa Fe, Argentina*

The aim is to determine the age at which carcinoma in situ and dysplasia occur for comparison with findings of authors elsewhere, using a sample group consisting of all 'healthy' patients seen at the Department of Gynecology. Data concerning the age at disease onset will be taken from the Registry. At the beginning of this study only age was considered; in the last months, parity and beginning of sexual relations have been added.

A MORTALITY STUDY OF NICKEL WORKERS IN ONTARIO

R.S. Roberts, McMaster University, Dept. of Clinical Epidemiology & Biostatistics, *1200 Main St. W., Hamilton, Ontario, Canada* L8S 4L8

This study ultilizes a fairly conventional historical prospective design to compare mortality patterns in nickel workers over a 27 year follow-up period. The study cohort consists of approximately 70,000 men working at Sudbury and Port Colborne. Eligible subjects are males with six months or more of accumulated service who worked for the company (or who were receiving a pension) on or after 1 January 1950. The mortality experience of these men through to the end of 1976 will be ascertained from the Statistics Canada registry of death certificates using a record linkage procedure based on full name, date of birth and 'last known alive' date. A series of tactics are being undertaken to estimate the accuracy of the matching. The analysis of this data will relate features of the detailed occupational histories of these men to cause-specific mortality. Of particular interest are the relationships of cumulative nickel sulphide and nickel oxide to respiratory cancer, but other cancers and contaminants will also be considered. In addition, exposure in terms of years of duration in particular occupations (i.e., the sinter plant) will be analyzed.

A STUDY OF MALIGNANCY AND OTHER ASBESTOS-RELATED DISEASES IN RELATION TO CROCIDOLITE MINING AND ENVIRONMENTAL EXPOSURE AT WITTENOOM GORGE

M.S. Hobbs, University of Western Australia, Unit of Clinical Epidemiology, *Nedlands, W. Australia 6009, Australia*

The aim of the study is to determine the incidence of mesothelioma, bronchogenic carcinoma and other malignant tumors in workers previously employed in mining and milling crocidolite at Wittenoom Gorge, Western Australia, between 1942 and 1966, in relation to duration of exposure and smoking habits. The risk of mesothelioma in the relatives of workers and other Wittenoom Gorge residents not directly involved in mining crocidolite will also be assessed. Work is continuing to determine the vital status and present whereabouts of approximately 6,500 men formerly employed at Wittenoom Gorge through electoral rolls, other population registers and cancer and death registers in different Australian States. Commencing in 1979 a questionnaire will be sent to all former Wittenoom Gorge workers so far located to obtain further details concerning occupation and smoking habits. Respondents will be followed for as long as necessary to determine the interaction between crocidolite exposure and smoking in relation to the development of bronchogenic carcinoma. This questionnaire will also seek information concerning relatives of former asbestos workers also living at Wittenoom Gorge. This will be supplemented, if possible, by information from local government and school records to establish a roll of persons not directly involved in processing crocidolite but possibly at risk of developing mesothelioma from environmental exposure. Procedures will be established to monitor this cohort for the future development of mesothelioma.

INCIDENCE OF TESTICULAR TUMORS WITH EMPHASIS ON POSSIBLE RURAL PREPONDERANCE AND OCCUPATION

T.F. Sandeman, Peter MacCallum Hospital, Urological Service, *278 William St., Melbourne, Victoria 3000, Australia*

Previous surveys of the testicular tumor population presenting to the Peter MacCallum Clinic have suggested an increased incidence of patients from rural areas. Articles published since then have confirmed this trend overseas. Futhermore, evidence in the literature indicates occupational risks for a large number of cancers. Two studies are being carried out: (1) A survey of all testicular neoplasms in the State of Victoria from 1950 to 1978, using records from pathology laboratories, to determine any increase in incidence and possible rural preponderance. (2) A case-control study of cases at Peter MacCallum since 1952, investigating residence (metropolitan, town or rural), occupation, place of birth, religion and possible exposure to carcinogens. All cases have been histologically classified to reveal relationships according to classification. Retrospective studies covering all the available case material are being carried out (a) to increase the numbers and (b) to detect any change in trends, and a survey of pathologists' records is being conducted.

ANALYSIS OF COMPUTERIZED DATA ON MALIGNANT MELANOMA

H.M. Shaw, University of Sydney, Dept. of Surgery, *Sydney, N.S.W. 2006, Australia*

A detailed study of malignant melanoma is being made from two points of view: factors in the host and tumor that influence the behavior of the tumor, i.e., disease-free periods and site and type of metastases when they develop. The factors being investigated from the existing records include: (1) identification of high risk individuals; (2) role of sunlight exposure. Studies from the United States and Europe indicate an inverse relation between incidence of melanoma and geographic latitude. However, there appears to be little correlation between morbidity and mortality. Because morbidity has increased more than mortality, there is a need to establish whether: (a) the increase in incidence is indeed a real effect or an artifactual one, resulting from earlier diagnosis and the more frequent removal of superficial tumors, and (b) melanomas induced by sun exposure have a lower degree of malignancy than those always covered by clothing; (3) tumor factors possibly unrelated to sunlight exposure. Morbidity may have increased more than mortality due to changes in the biological nature of the tumor, such as histological type, grade of mitotic activity, level of invasion or tumor thickness; (4) patterns of dissemination of melanoma. It is important to determine why melanoma spreads by either rapid hematogenous transmission, by slower direct lymphatic extension or extension through successive echelons of local and regional lymphatics.

DIET, ALCOHOL, AND HORMONAL STATUS IN COLORECTAL CANCER

J.D. Potter, Commonwealth Scientific & Industrial Research Org., Div. of Human Nutrition, *Kintore Ave., Adelaide, S. Australia 5000, Australia*

Consumption of alcohol in Australia varies considerably between ethnic and social groups. Diet is presumed to be more homogeneous, which makes it less amenable to analytical study than alcohol. However, some critical dietary items may vary considerably within the population. It has been demostrated that the ratio of male:female incidence rate of colon cancer is about 1, whereas that for rectal cancer is around 2. Further it has been shown that nulliparity is a risk factor for colon cancer in a way similar to that for breast cancer. A case-control study investigating the relationship of both colon and rectal cancer separately, (paying particular attention to anatomical location) with dietary fat, dietary fiber, vitamins A and C and parity and hormonal status is now being undertaken. Cases are identified using a community-based cancer registry, while controls are drawn from the general community. Approximately 400 cases and 800 controls will be studied.

CENTRAL CANCER REGISTRY

N.J. Gray, Anti Cancer Council of Victoria, Central Cancer Registry, *90 Jolimont St., East Melbourne, Victoria 3002, Australia*

The Central Cancer Registry continually monitors hospital data from large hospitals in Victoria, covering an estimated 50% of cancers occurring. Clinical data are recorded by medically qualified registry personnel and follow-up to provide survival data is rigorous. The registry yields information on relative frequency as well as treatment trends and results, and is available as a case-identifying centre for retrospective epidemiological studies. A population-based registry is now being developed to register all cases of cancer within the State of Victoria to enable incidence and prevalence to be established. Registry data are made available to research workers on request and advice on statistical and epidemiological techniques is also given.

MONITORING THE OCCUPATIONAL ENVIRONMENT FOR CARCINOGENS - A PILOT STUDY IN MONTREAL

J. Siemiatycki, Armand Frappier Institut, Centre de Recherche de Epidemiologie et Medecine Preventive, *531 Blvd. des Prairies, Case Postale 100, Laval des Rapides, Quebec, Canada* H7N 4Z3

Of the thousands of chemicals in the occupational environment, only a score have at present been demonstrated to be human carcinogens. There is no human evidence one way or another for almost all of the others. The very large number of agents renders inadequate conventional 'one-factor-at-a-time' epidemiologic study methods (case-control or cohort). The objective is to establish an ongoing monitoring system capable of scanning the occupational environment to detect hitherto unsuspected human carcinogens. A case-control type methodology will be used. Cases will be adult male cancer patients hospitalized in the Montreal region. Several sites will be included and each will be analyzed separately. In the pilot study, controls for each site will be selected from among the cases with cancer of other sites. For each man a lifetime history of exposure to a large number of agents will be ascertained. An innovative approach will be developed to ascertain occupational exposures which the worker might not be able to report or recall. This will be based on a self-administered questionnaire followed by an in-depth interview and a matrix relating specific chemical exposures to specific jobs. The matrix will be developed in consultation with experts in the fields of chemical and industrial engineering. A worker's exposure history will be inferred from his job history and the matrix. The analyses will aim to identify high risk chemicals and workplaces. A two-year feasibility study will evaluate diverse aspects such as case ascertainment, data collection methods, and the statistical sensitivity of the system before a long-term system is established.

OCCUPATIONAL AND NON-OCCUPATIONAL RISK FACTORS OF SQUAMOUS CELL CARCINOMA OF SKIN IN THE MONTREAL REGION

F. Aubry, McGill University, Dept. of Epidemiology & Health, *3775 University St., Montreal, Quebec, Canada* H3A 2B4

Data from the Cancer Registry of the Province of Quebec indicate that skin cancer is one of the leading types of cancer in the Montreal region. Given that the two major risk factors of squamous cell carcinoma of the skin recognized in the medical literature are sunlight exposure and the Celtic characteristics of people and that these factors are not particularly marked in the Montreal region, the possibility exists that other risk factors, particularly occupational, could play role. The objective of this case-control study is to assess the relative risk associated with occupational and non-occupational known and suspected risk factors of squamous cell carcinoma of the skin diagnosed in the Montreal region, specifically occupational exposure to sunlight and/or to chemical agents and radiations. The cases are defined as all cases of squamous cell carcinoma of the skin diagnosed during the two years preceding the beginning of the study in the pathology departments of Montreal hospitals. Two controls matched for sex and age with each case will be selected from among pathology records at the same hospital at which the case was found. The controls will be subjects in whom a pathological diagnosis will have been made for skin condition which is non-malignant and which is not known to be related to the risk factors of squamous cell carcinoma of the skin. Cases of pemphigus vulgaris, bullous pemphigus, intradermal naevus and lichen planus will thus be included. The total number of cases in this study is estimated between 400 and 800. A postal questionnaire on occupation and exposure to environmental factors will be sent to each case and each control and telephone calls will then be made to complete missing information. Data will be analysed by means of a discriminant analysis.

LATENT PERIODS OF LUNG CANCERS IN CHRYSOTILE MINERS AND MILLERS

F.D. Liddell, McGill University, Dept. of Epidemiology & Health, *3775 University St., Montreal, Quebec, Canada* H3A 2B4

The aim of this study is to investigate the variation in period from first occupational exposure to death in 244 deaths from lung cancer up to the end of 1975 among males in the 'Quebec Asbestos Mortality Cohort' consisting of 10,939 men born 1918 through 1920 who worked for at least a month in the asbestos mines and mills of Quebec. Account will be taken of the full histories of exposure, incorporationg the proportion of each year the man was employed and the average concentration of asbestos, yearly, measured in fibers per cc, and complete smoking histories obtained by questionnaires already completed but requiring recording. Attention will also be paid to such matters as eras of birth and of death, and attempts will be made to cast light on the mechanisms of carcinogenesis.

LUNG CANCER MORTALITY IN ALUMINUM REDUCTION WORKERS

G.W. Gibbs, McGill University, Inst. for Mineral Industry Research, Occupational Health & Safety Unit, *Gault Estate, Mont St. Hilaire, Quebec, Canada* J3G 4S6

The study aims to determine the lung cancer mortality of workers in three aluminum reduction plants for the 4 year period 1 January 1974 to 31 December 1977 and to examine the relationship between lung cancer mortality and length of employment and level of tar exposure. The methods to be applied are identical to those in an earlier study of lung cancer mortality (1950-1973) currently in press. The populations under study consist of 2 cohorts employed at aluminum reduction plants, one of 5,406 workers who were working at plant A on 1 January 1950 and the other of 485 workers who were working at plant B on 1 January 1951. The mortality experience from lung cancer for this population was studied to 31 December 1973. The period of observation will now be extended to 31 December 1977. The pattern of mortality for the 2 periods 1950-1973 and 1974-1977 will be examined to determine any change in the relationships between lung cancer mortality and tar exposure.

CANCER MORTALITY AND DRINKING WATER QUALITY

D.T. Wigle, Canadian Dept. of National Health & Welfare, Lab. Centre for Disease Control, *Tunneys Pasture, Ottawa, Ontario, Canada* K1A 0L2

Cancer mortality rates by sex and site for 104 municipalities will be correlated with water quality. Water samples have been analyzed to determine concentrations of the following: amphibole asbestos, chrysotile asbestos, trihalomethanes, total organic carbon, nitrilotriacetic acid, lead, cadmium, zinc, copper, calcium, magnesium and total hardness. For most municipalities, mortality data are available for at least the past 20 years. Cancer and other disease mortality rates will be correlated with the water quality data listed above plus other factors (year of fluoridation, source of water).

IDENTIFICATION OF OCCUPATIONAL RISK FOR COLORECTAL CANCER

J.M. Vobecky, Universite de Sherbrooke, Faculte de Medecine, Dept. des Sciences de la Sante Communautaire, *c/o Centre Hospitalier Univ., Sherbrooke, Quebec, Canada* J1H 5N4

A cluster of five cases of cancer of the large intestine has been observed. The patients had several features in common, including work in the same department of a textile plant. By examining the frequency of colorectal cancer in the population, on the one hand, and these common features, in particular the same long term occupational exposure, on the other, the study attempted to determine whether this clustering was only due to chance or to occupational exposure. A study was done on occupational history, familial history of cancer, bowel habits, precursor diseases, and predisposing conditions for all colorectal cancer patients contracting the disease from 1965 to 1976, in the area where the plant is located and in the neighboring areas. Results, based on 1,600 colorectal cancer cases, show that colorectal cancer was 10 times more frequent among synthetic textile workers than in the non-exposed population (Gastroenterology, 75, 221, 1978). In order to establish the etiological nature of this association, a case-control study has been undertaken. The control groups include patients with cancer other than colorectal cancer, patients with diseases other than cancer, and matched neighborhood controls. The on-going phase of the work will establish whether or not an elevated risk of colorectal cancer is associated with employment in any particular part of the plant.

FRENCH MESOTHELIOMA REGISTER

J. Bignon, Centre Hospitalier Intercommunal de Creteil, Service Hospitalier Universitaire de Pneumologie, *40 Ave. de Verdun, 94010 Creteil, France*

To date 197 proved cases of mesothelioma (mainly pleural) have been reported for the period 1965-1978, a moderate increase over time being noted. Occupational and para-occupational asbestos exposure was recorded in 77 percent and 3 percent of registered cases respectively. As the number of cases notified to the register is obviously an underestimate, it is intended to evaluate the annual incidence of this tumour by retrospective registration. Relationships with asbestos exposure and with other pollutants will be sought, and case-control studies for a dose-response relationship with asbestos carried out using retrospective inquiries and measurements of fibres in tissue.

ESTABLISHMENT OF A REGISTRY FOR DIGESTIVE TRACT TUMORS IN THE DEPARTMENT OF CALVADOS

C. Chuberre, Centre Hospitalo Universitaire, Service de Chirurgie Digestive, *Av. de la Cote de Nacre, 14033 Caen, France*

This Registry has been established to clarify the frequency of these cancers according to site, age, sex, occupation, alcohol and tobacco consumption; to define high risk population groups for each site; and to provide information on the current status of screening (warning signs, diagnostic means, time lag between first symptom and diagnosis and between diagnosis and death). Data are collected from physicians, gastro-enterologists, surgeons, pathologists in towns, hospitals (university hospitals, cancer centres, private and public hospitals), health insurance bodies and the Department Directorate for Health and Social Welfare. Only cases of digestive cancer which have occurred since 1 January 1978 in patients residing in Calvados are included.

CALVADOS CANCER REGISTRY

J.M. Robillard, Centre Regional Francois Baclesse, Service de Statistiques, *Rte. de Lion-sur-Mer, 14018 Caen, France*

The registry compares cancer morbidity in the Department of Calvados with that in the French regions of Bas-Rhin and Doubs, in other regions bordering France (Geneva, Lausanne, Neuchatel, Saragossa) and in more distant parts (Warsaw, Connecticut, Cuba, southern England, etc.). Morbidity time trends are estimated and compared with those observed in other registries. The geographical distribution of cancer within Calvados is examined to study possible etiological factors (e.g. predominance of lung cancer in areas with asbestos industries). The Registry records cancer cases in the Department as accurately as possible and assists with the planning of screening and prevention in Lower Normandy.

PRECANCEROUS CONDITIONS OF THE STOMACH

K.S. Varis, Helsingin Yliopisto, Dept. of Medicine, *Fabianinkatu 33, SF00290 Helsinki, Finland*

Atrophic gastritis is a well known risk factor of gastric cancer and severe atrophic gastritis of the body (SAGB) probably carries the highest risk. In the atrophic mucosa tissue metabolism is altered, the intestinal mucosa acquiring absorptive characteristics (absorption of carcinogens). Cell maturation and kinetics are disturbed leading sometimes to the development of epithelial atypia, and the associated achlorhydria may facilitate the development of carcinogenic nitroso-compounds intragastrically. The determination of serum pepsinogen group I (Radio-immuno-assay-method of Samlofi), with a very high sensitivity and specificity, is used as a screening method for SAGB. Serum pepsinogen group I determination will also be carried out in a sample of patients with gastric carcinoma to examine possible correlations between SAGB (low serum pepsinogen group I), and the localization and histological type of gastric carcinoma. 100 subjects without any major gastric pathology, such as polyps, peptic ulcer or gastric cancer, will also be studied as part of an international multicentre study proposed by IARC. Gastric biopsies from antrum and body, and samples of gastric juice and blood are taken for estimation of N-nitroso compounds in people living in low or high risk areas.

BENIGN BREAST DISEASE - NATURAL HISTORY AND RELATIONSHIPS TO BREAST CANCER

D.V. Vakil, University of Toronto, Faculty of Medicine, Dept. of Preventive Medicine & Biostatistics, *92 College St., Toronto, Ontario, Canada* M5S 1A8

This retrospective cohort study is designed to delineate the natural history of benign breast lesions, and to determine the ways in which the benign and malignant conditions relate in the same individuals. A cohort of 1,713 women who were biopsied between 1968 and 1973 at the Toronto Western Hospital for possible breast cancer and were found to have benign breast disease has been assembled. Genetic, epidemiological and pathological information will be obtained on these women. This data will be analyzed to assemble descriptive information about the natural history of the benign breast lesions in all patients and also in the patients stratified by histological type of the lesion, and by the presence of microcalcification in the mammogram. These women will be followed up to the year 1981 (8 to 13 years) to (1) obtain additional information about the postulated risk factors of breast cancer and (2) determine the subsequent development of benign or malignant breast diseases among them.

EPIDEMIOLOGICAL STUDY OF BLADDER CANCER

A.B. Miller, University of Toronto, *Medical Sciences Bldg., Toronto, Ontario, Canada* M5S 1A8

A recent case-control study of the epidemiology of bladder cancer conducted by the NCIC Epidemiology Unit produced a number of important findings. The current study's objective is to re-evaluate these findings in a second case-control study conducted in different geographical areas in Canada. Areas where occupational causes may be more important, the roles of tobacco, particularly the differential effect of filter and regular cigarettes, artificial sweeteners, instant and regular coffee in males as well as females, hair dyes, and the association with non-public water supplies will be studied. The study is population-based with case and control acquisition from the whole of Alberta and from southern Ontario including the areas of metropolitan Toronto, Kingston, Windsor, London, and Hamilton. All newly diagnosed

cases of bladder cancer in the areas included in the study are being identified. An equal number of age- and sex-matched controls will be obtained from population registries. All cases and controls are interviewed in their own homes with a questionnaire similar to that utilized in the first study.

NATURAL HISTORY OF DYSPLASIA OF THE UTERINE CERVIX

A.B. Miller, University of Toronto, *Medical Sciences Bldg., Toronto, Ontario, Canada* M5S 1A8

In most models of the natural history of squamous carcinoma of the cervix, dysplasia is regarded as the first recognizable pathological process in an orderly progression from normal to malignant epithelium. Since dysplasia does not always become malignant, there is need to clarify the extent to which regression forms part of the natural history of dysplasia. The present study aims at seeking information on the natural history of cytologically identified but untreated dysplasia in comparison with a sample of normal women with smears examined in the same laboratory. An estimated 10,000 women in the case series of moderate or severe dysplasia and 30,000 in the control series will be included. Information is also being sought on the possible association of oral contraceptive use and the risk of progression of dysplasia. Data extraction is currently under progress.

EPIDEMIOLOGICAL STUDY OF LARYNGEAL CANCER

A.B. Miller, University of Toronto, *Medical Sciences Bldg., Toronto, Ontario, Canada* M5S 1A8

The study is designed to investigate the contribution of known and suspected aetiological factors to laryngeal carcinoma. It is hypothesized that there is an association between laryngeal carcinoma and the smoking of tobacco and that there is a reduced risk for smokers of filter cigarettes. It is also proposed that there is a synergistic effect between alcohol consumption and the smoking of tobacco. A further hypothesis is that there is an association between laryngeal cancer and exposure to asbestos in the environment and occupationally, especially for those who smoke cigarettes. It is also hypothesized that there is an association between cancer of the larynx and exposure to nickel refining and processing. The study is a case-control study with data on past events and exposure obtained from cases and controls by means of a detailed questionnaire which is administered personally to cases and controls in their homes. The study population consists of all newly diagnosed cases with carcinoma of the larynx, March 1, 1977, to April 31, 1978, resident in Southern Ontario and the Sudbury, and North Bay areas in Northern Ontario. Controls are matched to cases by age (plus or minus five years), sex, and neighborhood of residence. Controls are obtained by door to door survey. At the end of 16 months of interviewing, a total of 130 case-control pairs have been interviewed. It is anticipated that a total of 200 case-control pairs will be available for analysis.

THE PREVALENCE OF BREAST CANCER AMONG FEMALE FACULTY MEMBERS AND FACULTY WIVES

B.J. Morrison, University of British Columbia, Dept. of Health Care & Epidemiology, *6174 University Blvd., #300, Vancouver, British Columbia, Canada* V6T 1W5

The object is to determine the prevalence rate of breast cancer among women who are faculty members and among the wives of the male faculty members and compare it with the expected rates from provincial incidence figures. Because of their high socioeconomic class and late child bearing, this group of women may be at a high risk. The rates will be correlated with age at first pregnancy to see if there is an excess rate after correction for this has been made. All faculty members were sent a brief questionnaire and to date over 70% have responded. The data have not yet been tabulated.

ANALYSIS OF CERVIX UTERI CANCER MORTALITY RATES IN CHILE

A. Dabancens, Universidad de Chile, Servicio de Citopatologia y Control de Cancer, *1058 Av. Bernardo O'Higgins, Santiago, Chile*

The study evaluates the National Cervix Uteri Cancer Control Programme. Standardized mortality rates for this cancer in different regions of the country are related to the percentage of women screened in these regions. A reduction of more than 70% in mortality rates, taking epidemiological factors into account, has been observed in the screened population. The rates per 100,000 for women over age 20 from 1970-1977 in two areas of Santiago show, for unscreened populations, expected rates of 27.90 and 24.54 and observed rates of 47.84 and 27.46, while in the screened populations expected rates are 17.40 and 19.43 and observed 4.64 and 5.71. The study continues.

INTESTINAL MICRO-ECOLOGY IN NORDIC COUNTRIES

O.M. Jensen, Centre International de Recherche sur le Cancer, Division of Epidemiology & Biostatistics, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France* (00128)

The project continues to collect information in relation to two sets of hypotheses: (1) Metabolic hypothesis - specific dietary consituents, e.g., fat or type of meat, are related to fecal bacterial flora, metabolities of bile acids and steroids in the feces and in turn to colon cancer risk differences. (2) Fiber deficiency hypothesis - it has been postulated that high intake of fiber (especially from cereals) results in increased fecal bulk and is protective against colon cancer. These hypotheses are being examined in a collaborative project comparing urban and rural populations in Denmark and Finland. The populations are compared in terms of present diet, including dietary fiber, mouth-anus transit time, fecal bacteria, steroids and mutagenicty, other characteristics, such as fecal weight.

DETERMINATION OF A RISK LEVEL FOR BREAST CANCER AND ITS APPLICATION TO MASS SCREENING

A.G. Bremond, Hopital Edouard Herriot, Clinique Gynecologique, *Pl. d'Arsonval, 69374 Lyon Cedex 2, France*

Nationwide X-ray screening is both impracticable and unadvisable. If high risk women were identified, this examination could be restricted to a smaller number of patients. On the basis of known epidemiological data, a double prospective survey can be carried out among cancer-free control women and those who have had breast cancer. The risk level, determined through a computer program, should select 80 percent of women with cancer and not apply to more than 50 percent of controls.

PRECANCEROUS LESIONS OF THE ESOPHAGUS IN HIGH- AND LOW-RISK AREAS FOR ESOPHAGEAL CANCER

N. Munoz, Centre International de Recherche sur le Cancer, Interdisciplinary Programme & International Liaison, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France*

The objective of this study is to determine the type and prevalence of precancerous lesions of the esophagus in populations with high and low rates for esophageal cancer. At autopsy, esophagi have been collected from patients dying of diseases other than cancer of the esophagus. The specimens have been processed and examined by the pathologists participating in the study, using standard techniques. Slides from each case are sent to the IARC for circulation among the pathologists. A blind histopathological evaluation of these will be made, using a standard protocol.

HISTOLOGY, IMMUNOPATHOLOGY, AND VIROLOGY OF MALIGNANT LYMPHOMAS (EPIDEMIOLOGICAL COMPARISON BETWEEN WEST GERMANY AND COLOMBIA)

G. Krueger, Universitat zu Koln, Immunopathology Section, *Cologne, Federal Republic of Germany*

The objective of the study is to identify various histological and immunological types of malignant lymphomas and correlate their incidence with the frequency of infectious diseases in general and with EBV infection. In particular there is an obvious difference in the occurrence of various types of malignant lymphomas between West Germany and Colombia. There also appears to be a difference in the incidence of infectious diseases between both countries, both bacterial and viral. It is expected that certain types of malignant lymphomas will increase with the increased frequency of infections. The study will identify such tumours and analyse their pathogenesis by comparing the results with those from experimental studies on lymphomagenesis.

MORTALITY STUDY ON THE OCCUPATIONAL RISK OF ACRYLONITRILE PROCESSING

A.M. Thiess, Badische Analin & Soda Fabrik Ag, Abt. fuer Arbeitsmedizin und Gesundheitsschutz, *Brunckstrasse 56, 6700 Ludwigshafen, Federal Republic of Germany*

This study is designed to evaluate the possible carcinogenic potential of acrylonitrile as an occupational risk substance since evidence exists that acrylonitrile may be the cause of lung and colon cancer amongst workers exposed to the chemical. The warning of NIOSH that the product should be handled as a cancer-causing agent in humans is based on preliminary tests on animals and on an epidemiological study carried out in workers exposed to the chemical. The differential mortality of workers involved in the processing of acrylonitrile at different plants of BASF Ludwigshafen is investigated by a cohort study including all personnel ever employed at the site of manufacture taking into account the possibility of mixed exposures. This problem of mixed exposure makes the evaluation more difficult.

MORTALITY AND MORBIDITY SURVEY OF OCCUPATIONAL RISK OF ETHYLENE AND PROPYLENE OXIDE IN CHEMICAL PRODUCTION AT BASF, LUDWIGSHAFEN, GERMANY

A.M. Thiess, Badische Analin & Soda Fabrik Ag, Abt fuer Arbeitsmedizin und Gesundheitsschutz, *Brunckstrasse 56, 6700 Ludwigshafen, Federal Republic of Germany*

Ethylene oxide (EO) is known to be a mutagen in various biological systems like bacterias, animal and human tissues. This led to a suspicion that EO might be a potential carcinogenic risk. A cohort study was designed to assess cancer incidence in those occupational groups which have been exposed to both ethylene and propylene oxide. The chemical workers ever exposed to the substance are followed up for mortality experience (cause of death) and for morbidity. The follow-up includes careful tracing of retired and resigned persons. The problem of possible mixed exposure has to be taken into consideration.

STUDY OF THE POSSIBLE PREVENTIVE EFFECT OF BCG AGAINST CANCER IN ADULTS

L. Frappier Davignon, Armand Frappier Institut, Centre de Recherche en Epidemiologie et Medicine Preventive, *531 Blvd. des Prairies, Case Postale 100, Laval des Rapides, Quebec, Canada* H7N 4Z3 (01345)

Studies have shown that BCG may have a non-specific preventive effect against mortality due to leukemia in children aged 0 to 4 years. This cohort study aims to determine if BCG could have a preventive effect against cancer in adults by comparing mortality and morbidity from cancer of all types among vaccinated and unvaccinated nurses. Names and addresses of all nurses graduated in the province of Quebec between 1952 and 1967 were obtained. A questionnaire was sent to each. This questionnaire included questions on age, date of graduation, marital status, BCG vaccination status, names of diseases of all kinds diagnosed since graduation, date of the event, place of diagnosis and treatment, name of physician, smoking habits, number of preg-

nancies and abortions and finally name and cause of death of classmates known to have deceased since graduation. The BCG vaccination status was verified in the central BCG record of l'Institut Armand-Frappier. Information has been received from 12,856 nurses of a possible total of 21,000, and 453 deaths have been reported. These data will be analyzed, taking into consideration vaccination status, age and time since vaccination.

REGISTRATION OF WOMEN WITH PRIMARY AND SECONDARY GENITAL HERPES SIMPLEX VIRUS (HSV) INFECTION
B.F. Vestergaard, Kobenhavns Universitet, Inst. of Medical Microbiology, Dept. of Clinical Virology, *22 Juliane Mariesvej, DK2100 Copenhagen OE, Denmark*
Recent observations indicate that women suffering from primary genital HSV type 2 infection represent a high risk group for later development of carcinoma of the uterine cervix. The development of a simple, sensitive and reliable enzyme-linked immuno-specific assay (ELISA) for the exact titration of herpes simplex virus type 1 and type 2 specific antibodies in human sera has made it possible to perform serological HSV type-specific diagnosis of clinical cases of genital HSV infections and identify four categories of patients: (1) Primary genital herpes caused by HSV type 2 (HSV infection in an individual who has never had HSV infection before); (2) primary genital herpes caused by HSV type 1; (3) secondary genital herpes caused by HSV type 2 (genital HSV in an individual who has previously had HSV type 1 infection); (4) wrong clinical diagnosis (i.e., the serological result indicates that the patient did not have an HSV infection). It is planned, in a period of three years, to diagnose and register as many of the genital HSV infections as possible - hopefully at least 50% of all cases in Denmark seeking medical care. The later follow-up of the registered cases of genital HSV infection will be performed under the screening programs for cervical carcinoma presently being developed in Denmark. The objective of the study is, by a large-scale prospective investigation, to obtain valid information about: (1) The incidence of genital HSV infection in Denmark and the distribution of primary and secondary cases, and (2) the risk of later development of carcinoma of the uterine cervix.

3.1711,
EPIDEMIOLOGIC STUDIES ON MALE LUNG CANCER IN NORTHERN SWEDEN
L.G. Larsson, Regionsjukhuset, Dept. of Oncology, *90185 Umea, Sweden*
In a study of the geographical distribution of all new male lung cancer cases in the three northernmost counties in Sweden between 1959 and 1971 great differences were found between different regions. Some communities with mining districts or other heavy industry had age-adjusted incidence rates 10-15 times higher than more rural communities. The occupational profile of te cancer cases is being compared with that of a control series matched by age and place of residence. Information about occupation is obtained both for the cases and for the randomly selected controls through the general population register. For deceased male lung cancer cases registered in the same region from 1972 to 1977, a more detailed case-control study is being performed based on questionnaires to relatives about occupation, employment and smoking habits.

3.1712,
MORTALITY OF SMOKERS AMONG SWISS PHYSICIANS
O.R. Gsell, Universitat Basel, Dept. fuer Innere Medizin, *Zwinglist. 21, 9000 St. Gallen, Switzerland*
The mortality rates and causes of death for smokers, nonsmokers, and past smokers in Swiss physicians have been examined as part of a study of 1,212 deaths in 3,740 physicians from 1955-1973. All of the 40 doctors with bronchial carcinoma were smokers. The death rate for myocardial infarction in smokers was high for the age-group 35-55, returning to normal over the age of 75. The similarity of mortality rates in cigar and pipe smokers in Switzerlnd with those of non-cigarette smokers (around 20% of the total) is of special interest. The study continues.

3.1713,
POSTMENOPAUSAL ESTROGEN TREATMENT AND ENDOMETRIAL CANCER
I.R. Persson, Uppsala Universitet, Dept. of Obstetrics & Gynecology, *Box 256, S75105 Uppsala, Sweden*
It has been hypothesized that estrogens are related to development of postmenopausal endometrial cancer. Numerous American case-control studies have shown a substantial increase of risk in connection with estrogen replacement therapy. The present study is a prospective one which will follow a sample of some 30,000 estrogen-treated postmenopausal women during an observation period of at least five years to ascertain the incidence of endometrial cancer. The observed incidence in this cohort will be compared to the expected one which will be computed from available cancer statistics. There will be additional studies in this cohort regarding the incidence of mammary cancer and also deep vein thrombosis and gallbladder disease. The large cohort is established by collecting all estrogen prescription forms from a defined geographical region in the center of Sweden. From these prescription forms the identity-number (a ten-digit number) will be collected and stored with the help of computer facilities. All new cases of endometrial cancer will be collected from different pathology departments which serve the same geographical region. All hysterectomized women in the cohort will be excluded by referring to a special computer-based admission diagnoses register. All cases of endometrial cancer will be examined and interviewed to study the distribution of known risk factors. This will be done in samples of the total estrogen cohort and samples from a non-treated healthy population.

3.1716,
THE EFFECT OF GYNECOLOGICAL SCREENING PROGRAMS ON THE INCIDENCE OF CERVICAL NEOPLASIA
L.G. Lindberg, University Hospital of Lund, Cytodiagnostic Laboratory, *EB-blocket, S22185 Lund, Sweden*
Cytological screening programs have a certain effect on the incidence figures of cervical neoplasia, both pre-invasive and invasive. However, a significant effect on mortality figures has been difficult to establish. Using a computerized program and the unique person identification number long accepted by everyone in Sweden, every single investigation and single individual can be easily followed. Preliminary figures indicate that a significant effect can be demonstrated much earlier than previously found among women actively taking part in a screening program.

WOOD WORKERS AND CANCER
B. Esping, University of Linkoping, University Hospital, Dept. of Occupational Medicine, *58185 Linkoping, Sweden*
An excessive incidence of cancer of the nose has been found among wood workers. There are also some indications of an excessive incidence of malignancies elsewhere, but few systematic studies are available. Malignancies of other sites, particularly of the respiratory system, will, therefore, be studied to examine the possible relationship to wood dust exposure. Both the case-control and the cohort approach will be applied in two studies. Various types of wood will be studied with regard to their potential cancer producing properties.

3.1719,
HERBICIDE EXPOSURE AND CANCER INCIDENCE AMONG RAILROAD WORKERS

O. Axelson, University of Linkoping, University Hospital, Dept. of Occupational Medicine, *58185 Linkoping, Sweden*

An earlier report (Axelson and Sundell, Work Environ Health 11, 21-28, 1974) indicated a cancer hazard due to exposure to amitrole. Further evaluation has shown that exposure to phenoxy acids might also produce cancer (Axelson, Scand. J. Work Environ Health 4,85-89, 1978) and this is confirmed in another recent study on mesenchymal tumors and exposure to phenoxy acids and chlorophenols (Hardell, Laekartidnignen 75, 3535, 1978). It seems pertinent, therefore, to update the earlier study of a cohort of railroad workers to find out whether or not the increased cancer mortality continued after 1972.

3.1720,
MORTALITY AMONG FOREST WORKERS

O. Axelson, University of Linkoping, University Hospital, Dept. of Occupational Medicine, *58185 Linkoping, Sweden*

Several studies have shown an increased risk of cancer among people with exposure to various herbicides. Forest workers in Sweden have used phenoxy acids since the beginning of the 1950s and an evaluation of the mortality pattern might show particular features. The study will be descriptive in character and will show the proportional mortality for various causes of death. About 1,030 forest workers are known to have died during the study period, 1968-1977, as recorded on union registers. Using case-control techniques, a second part of the study will examine cause-effect relationships between cancer and exposure to phenoxy acids.

3.1721,
MINING, SMOKING AND LUNG CANCER

O. Axelson, University of Linkoping, University Hospital, Dept. of Occupational Medicine, *58185 Linkoping, Sweden*

An earlier report (Axelson and Sundell, Scand. J. Work Environ. Health 4, 46-52, 1978) has indicated a greatly increased lung cancer incidence among zinc-lead miners, as has also been found for iron ore miners in Sweden. It seems resonable to suppose that the occurrence of radon and radon daughters in the mines is primarily responsible for the increased lung cancer mortality among miners. Surprisingly it was found that non-smokers were affected as much or even more than smokers, although smokers, on an average, died of lung cancer before the age of 60, whereas non-smokers died over the age of 70. The explanation might be that smokers in underground work tend to get bronchitis, i.e. an increased thickness of the mucosa, which might protect against alpha radiation. Other mining groups are now being studied using a similar technique to confirm or refute earlier findings.

HOSPITAL BASED CANCER REGISTRY IN VISAKHAPATNAM

R. Chintala, Andhra Medical College, Dept. of Pathology, *Visakhapatnam 530002, India*

Palatal cancer is very common in this area in both sexes. Among males, penile cancer is also very common. A hospital-based cancer registry was established in 1976 to evaluate the frequency of these cancers. All cancer cases (histologically confirmed in the Department of Pathology) coming from a defined geographical area with a population of one million are collected. The minimum rates per thousand are calculated and standardized by age according to WHO.

3.1723,
CANCER OF THE BLADDER IN OPIUM ADDICTS

S. Behmard, Pahlavi University, School of Medicine, Dept. of Pathology, *Shiraz, Iran*

The main result of a case-control study of patients with bladder cancer at Shiraz (Pahlavi) University Hospitals was that the risk of developing cancer of the bladder in opium addicts is at least eight times greater than that of the normal population. A prospective study with screening of all opium addicts (by urine cytology for detection of early bladder carcinoma) was thus started at the University. The preliminary results indicate that the risk of developing cancer of the bladder is considerably higher in opium addicts than previously assumed. As of July 1978, 3,500 opium addicts had been screened. The controls, who do not take opium, number 1,750 and are matched by age and sex. A history of smoking habits is obtained. Fourteen histologically confirmed and previously unrecognized cases of bladder cancer have been detected. This early finding indicates that opium addiction should be considered as a carcinogenic agent for cancer of the bladder and further investigation is warranted. Schistosomiasis has not yet been reported in Fars Province and there is little industry.

MALIGNANT LYMPHOMA (NON-HODGKIN'S) IN EAST JAVA

D.S. Hoediasmoro, Universitas Airlangga, Faculty of Medicine, Dept. of Pathology, *Jalan Dharmahusada No. 47, Surabaya, East Java, Indonesia*

A retrospective study of non-Hodgkin's Malignant Lymphoma (nHML) in the Department of Pathology, Faculty of Medicine, Sourabaya (1973-1976) gave rise to a number of problems. There were many difficulties in investigating possible aetiological factors on nHML. The only factor that could be investigated and regarded as probably having an aetiological correlation was the socio-economic status of the nHML case. The possible correlation between the subtypes of nHML and their response to a certain mode of therapy was difficult to evaluate for various reasons including a limited budget. The study design has been changed and it is now intended to report the relative frequency of sub-types of nHML (histopathological classification), to investigate the age-distribution, to investigate the possible relation with socio-economic levels, and to investigate the geographical distribution. To increase the number of samples investigated, the anatomical site under study has been extended to the whole reticuloendothelial system and the area investigated has been enlarged from the Sourabaya area (town) to East-Java (province).

THE SWEDISH CANCER ENVIRONMENT REGISTRY

K. Wiklund, National Board of Health & Welfare, Planning Div., Dept. of Statistics, *Linnegatan 87, 10630 Stockholm, Sweden*

The persons with tumours who are entered in the Swedish Cancer Environment Registry are those contained in the Swedish Cancer Registry for a period 1961-1973 and verified as being registered in the 1960 Population and Housing Census. During the period from 1 January 1961 to 31 December 1973, the number of cases of cancer at sites 140-205 in the Registry was 376,015. Individuals were indentified by their personal identification number. On linking the files one per cent of entries in the Cancer Registry could not be traced. The information entered in the Registry, obtained from the 1960 Population and Housing Census, concerned the following: occupation, main occupation during the year, economic activity, occupational status, gainful employment, county, municipality or parish, location of place of work (county, municipality, parish), country of birth and education.

UTERINE CERVICAL DYSPLASIA AND ITS RELATION TO CERVICAL CANCER

P. Seth, All India Inst. of Medical Sciences, Dept. of Microbiology & Virology, *Ansari Nagar, New Delhi 110016, Delhi, India*

Evidence on the etiopathogenesis and biological behavior of cervical dysplasia is mostly controversial, however, it is generally accepted that less than five percent of cases progress to squamous cell carcinoma. A multifaceted approach to the study in two phases is planned, the first collecting data on the clinical, cytopathological and virological status of dysplasia cases and matched control women and the second following up dysplasia cases and controls to understand the biological behavior of the lesions and their progression to cervical cancer. So far serum samples from 186 patients with cervical dysplasia and 98 normal matched control women have been assayed for herpes simplex virus types 1 and 2 (HSV-1 and HSV-2) antibodies by the indirect hemagglutination (IHA) test. The distribution of HSV antibodies did not vary significantly among cases and controls. Ninety-five women with dysplasia and 39 controls were followed up for periods ranging from 6 to 36 months. The clinical and cytopathological findings of patients with cervical dysplasia were correlated with HSV-1 and HSV-2 antibody profiles in serum from the same patient. It was observed that (1) the majority of dysplasias reverted back to normal cytology during this period; (2) 14 patients had persistent dysplasia of the cervix and all of them had HSV antibodies; (3) three patients developed squamous cell carcinoma of the cervix and one developed adenocarcinoma. All the squamous cell carcinoma patients had HSV-2 antibodies, while patients with adenocarcinoma did not have HSV-2 antibodies. The study continues.

CANCER REGISTRY IN EASTERN INDIA

J. Roy Chowdhury, Chittaranjan National Cancer Research Centre, Dept. of Epidemiology/Pathology, *37 S.P. Mukherjee Rd., Calcutta, 700026, West Bengal, India*

There is no comprehensive cancer registry in Eastern India (West Bengal, Bihar, Assam and Orissa). Cancer patients from these states belonging to various groups with different socio-economic characteristics are referred to cancer hospitals and other hospitals of Calcutta for treatment. A cancer registry has been set up at the Epidemiology Dept. of Chittaranjan National Cancer Research Centre, Calcutta, to provide data for studying aetiology, epidemiology, treatment and end results of malignant diseases. The basic objectives of this registry include: (1) study of frequency distribution of different types of cancer in this area; (2) definition of high risk profiles; (3) determination of trends and aetiological factors.

CHRONIC ATROPHIC GASTRITIS AND INTESTINAL METAPLASIA IN THE HUNGARIAN AND ITALIAN POPULATIONS

A. Bajtai, Postgraduate Medical School, Dept. of Pathological Anatomy, *Szabolcs u. 33/35, 1389 Budapest, Hungary*

Stomach cancer is very frequent in Hungary. The most important predisposing conditions are chronic peptic ulcer, chronic atrophic gastritis with or without intestinal metaplasia and gastric polyps. The main objectives of the study are to identify any links between these high risk lesions and gastric cancer, and the relation of these precancerous conditions to each other. It is proposed to undertake comparative studies in Italy including nitrosamine levels in gastric juices and their relation to the histological alterations of the stomach. Some 200 patients with the listed conditions are being followed as well as non-symptomatic controls.

HISTOLOGICAL CLASSIFICATION OF TUMOURS IN ICELAND ACCORDING TO THE WHO CLASSIFICATION

J. Hallgrimsson, Haskola Islands, Dept. of Pathology, *Ingolfsstraeti 5, Reykjavik, Iceland*

This is a comprehensive study of tumours and tumour-like lesions in Iceland according to the World Health Organization's International Histological Classifications of Tumours. All tumours occurring in the country in the period 1955-1974 will be classified and when desirable, tumour-like lesions at some sites will be included. The results will be reported in a series of papers. This will represent a standard approach that is hoped to yield valuable data on tumours, their incidence and comparisons with other geographic areas. At the same time information will become available on the implementation of the WHO classifications. The WHO has given both scientific and financial support to this work.

ESTROGEN PROFILES IN DAUGHTERS OF BREAST CANCER PATIENTS IN GREECE

D. Trichopoulos, University of Athens, School of Medicine, Dept. of Hygiene & Epidemiology, *Odos Panepistimiou 30, Athens 609, Greece*

To account for the major features of the epidemiology of breast cancer, a hypothesis has been developed linking breast cancer risk to oestrogen metabolism. The hypothesis postulates that women who, during the early years of reproductive life, metabolize a low proportion of their oestrogen to oestriol are at high risk of breast cancer during the remaining years of their lives. Since daughters of breast cancer patients are at increased risk of breast cancer, it should be expected that these women would have low oestriol ratios. Urine samples are being collected from 100 daughters of breast cancer patients hospitalized in Athens. Estrogen profiles and other hormone metabolites are being measured in Melbourne or Boston.

THE CHRACTERIZATION OF RISK CONDITIONS OF GASTRIC CARCINOMA AND THEIR DYNAMIC BEHAVIOR IN REPRESENTATIVE SAMPLES

M. Siurala, (No Performing Organization Reported), *Finland* (00853)

The epidemiology and dynamic behavior of atrophic gastritis and its relation to gastric carcinoma have been studied in 301 first-degree relatives of index patients with gastric carcinoma and 358 age-and sex-matched relatives from a large Finnish population (Scand. J. Gastroenterol. 14: 129-139, 1979 and Acta Pathol. Microbiol. Scand. A 87: 457-462, 1979). The epidemiological and cell kinetic behavior of intestinal metaplasia and epithelial dysplasia are now being studied in the same population with the addition of all cases diagnosed at a gastroenterological department. The dynamics of Hydrochloric Acid (HCl) secretion on a population level are also being examined in this population. The dynamics are evaluated by mathematical methods based on stochastic assumptions and using a linear multicompartment modelling with analog hybrid computer technology.

CANCER MORTALITY ALONG A TRAFFIC ARTERY

W. Blumer, (No Performing Organization Reported), *Switzerland* (01296)

During an observation period of 18 years it was found that cancer mortality among all persons living adjacent to a highway was six times higher than that of the inhabitants of a traffic-free quarter. The soil content of polycyclic hydrocarbons along the traffic artery was 12 times greater than in the traffic-free section, and it could be proved that these hydrocarbons originated from automotive emissions. In the course of the next few years the condition of the still surviving inhabitants adjacent to the traffic artery will be examined. The possibility that other factors could be responsible for the excessive frequency of deaths due to cancer along the traffic artery will also be considered. Further analyses will determine whether a decrease in emissions and therefore decrease in cancer mortality take place.

AETIOLOGY OF PRIMARY SARCOMAS AND PULMONARY HAMARTOCHONDROMAS

C. Gebauer, Johannes Gutenberg Universitat Mainz, Medical Clinic, *Langenbeckstrasse 21, D6500 Mainz, Federal Republic of Germany*

The relation between carcinogenic exposures and the 104 pulmonary hamartochondromas diagnosed in 1959-1974, 192 histologically typed carcinomas of the lung in 1961 and 41 primary pulmonary sarcomas diagnosed between 1957 and 1974 in the regional pulmonary clinic of Zschadrass is being assessed. Controls are selected from a defined district, near Leipzig, with 35,300 inhabitants aged 20-80 years, which is within the area served by the clinic. This area contains an urban residential district, a rural area, and an industrial zone. Among the factors considered are the smoking of cigarettes; air pollution as determined by residence in urban, rural and industrial areas; exposure to radiation in underground mining; chronic lung diseases, notably chronic bronchitis, tuberculosis and silicosis; family history of cancer; blood groups. The various histological types of lung cancer are compared with the sarcomas and hamartochondromas.

COMPARATIVE STUDY OF ALCOHOLISM AND CANCER OF THE HEAD AND NECK

W.S. Lowry, Queens University of Belfast, Dept. of Oncology, *Belfast, Northern Ireland, United Kingdom*

One hundred patients with a diagnosis of head and neck cancer were investigated carefully for a history of alcoholism in the U.S.A. Most patients with cancer of the tongue, tonsil and oropharynx were alcoholics. About one half of the patients with supraglottic carcinoma were alcoholics. In the nasopharynx and true vocal cords, there was no association with heavy drinking. The study is now being extended to Ireland since the Irish ethnic group allegedly accounts for a considerable proportion of the American drinking problem. Initial results suggest that this may be ex-

aggerated at least as far as the cancer problem is concerned.

EPIDEMIOLOGICAL ASPECTS OF ASBESTOSIS AND MALIGNANT TUMORS

S. Yazicioglu, Diyarbakir University, Medical Faculty, Dept. of Chest Diseases, *Diyarbakir, Turkey*

Chrysotile and tremolite asbestos, freely dug, sold and used by inhabitants of some villages and towns in Turkey, leads to pleural calcification with the eventual complication of malignancy of the respiratory tract. This study aims to gather information concerning malignancies of the upper and lower segments of the respiratory tract and, to some extent, of the digestive system, among people of different socio-economic levels and geographic regions. The biological effects of asbestos will also be investigated in both humans and animals using clinical, experimental and laboratory methods, electron microscopy and mineralogical analysis of the biological material. The groups to be studied are: (1) hospital cases; (2) cases found in screening of the field; (3) animals such as mules and asses (used for transport); (4) laboratory animals such as rats and rabbits. Air and water pollution studies will also be carried out. This study will involve large control groups. Since Turkey is rich in different minerals, this investigation will reveal similar effects, if any, of other elements.

ENVIRONMENTAL FACTORS IN THE ETIOLOGY OF ESOPHAGEAL AND GASTRIC CARCINOMA

F. Memik, Bursa University, Medical School, Dept. of Internal Medicine, *Bursa, Turkey*

Esophageal and gastric carcinoma incidence is highest in eastern Turkey, an area which resembles the Caspian sea region in Iran in living conditions, eating habits and socio-economic status. The climate and some geological features are also similar. Iranian and Russian studies have shown that a great number of these cancers were found in patients of Turkish origin. A study is now taking place in the Marmara region where living conditions, diet and socio-economic status are entirely different from those in eastern Turkey. A cancer map and incidence data will be compiled to compare the two different regions.

RELATION BETWEEN REGIONAL DIETARY FIBER AND NUTRIENT INTAKES AND COLON CANCER MORTALITY IN GREAT BRITAIN

R. Williams, Medical Research Council, Dunn Clinical Nutrition Centre, *Trumpington St., c/o Addenbrookes Hospital, Cambridge CB2 1QE, England, United Kingdom*

There have been suggestions that the intake of dietary fiber is protective against neoplasms of the colon. Previous reports have dealt with international comparisons using estimates of crude fiber intake based on food production figures. This investigation explores associations between fiber intake and cancer of the colon within a defined region (Scotland, England and Wales). Figures for total dietary fiber consumption and the consumption of the components of fiber on a regional basis are computed from the National Food Survey estimates of food consumption (1969-73) and the fiber analyses of Southgate. Figures for nutrient intake and the consumption of certain foodstuffs are also included in the analysis. These are compared with truncated age-standardized death rates from cancer of the intestine (excluding rectum) for the same period.

A FOLLOW-UP STUDY OF WORKERS IN FLAX MILLS

P.C. Elwood, Medical Research Council, Epidemiology Unit, *4 Richmond Rd., Cardiff CF2 3AS, Wales, United Kingdom*

The aim of the study is to relate mortality in flax workers to occupation and dust exposure over a 16 year period. In 1962 a study was conducted by Elwood and others of 2,528 flax workers employed in Northern Ireland. A modified form of the Medical Research Council questionnaire was administered, simple respiratory measurements were made and a detailed survey of dust levels was conducted. An attempt is now being made to trace each worker seen in 1962. If dead, the certified cause of death will be ascertained and related to occupation, dust exposure and probably some of the measurements made in 1962.

MONOGRAPHS ON CLINICAL AND EPIDEMIOLOGICAL ASPECTS OF MALIGNANT DISEASE IN A POPULATION OF 5 MILLIONS

J.A. Waterhouse, Regional Cancer Registry, *c/o Queen Elizabeth Med. Ctr., Birmingham B15 2TH, England, United Kingdom*

A series of monographs is being prepared, each one dealing with a single site, or with a group of closely related sites, where, by examining at the same time both epidemiological and clinical features in extenso, an attempt is made to provide an overall view of the occurrence and treatment of the disease in the region as a whole. By including all cases, rather than a selected series from a central hospital, the degree of variation of treatment and survival can be shown. One of the results it is hoped to obtain is an improved sense of regional solidarity, leading to greater interest and participation in region-wide schemes to up-grade treatment standards and thus improve prognosis. Comparisons of incidence by geographical or other subdivisions of the region can also be used as possible indicators of etiological factors.

CORRELATIONS BETWEEN DIETARY FACTORS AND PRE- AND POST-MENOPAUSAL BREAST CANCER

B. Modan, Chaim Sheba Medical Center, Dept. of Clinical Epidemiology, *Bitan 27, Tel Hashomer, Ramat Gan, Israel*

Epidemiological studies have shown the possible role of nutritional patterns in the etiology of breast cancer. Our study will try to determine the role of diet and/or nutritional status in the incidence, pathogenesis and natural history of pre- and post-menopausal breast cancer. This study is based on 720 newly diagnosed cases of cancer of the breast and 1,440 matched controls. Each case will be matched to two types of control: (1) non-malignant and non-gastrointestinal surgical patients from the same wards and (2) neighborhood. Controls will be matched on age and year of immigration to Israel (within five years), and country of origin. Analysis will be done separately for the main ethnic groups, as well as for pre- and post-menopausal women. Correction for such factors as age at first pregnancy, parity, weight, and height will be applied. A list of 243 food items will be included in the questionnaire, comparison of cases and controls will pertain to: (1) individual food items and (2) groups of foods combined on the basis of common nutritional components.

ROLE OF INFANT FEEDING PRACTICES AND ENVIRONMENTAL FACTORS IN DEVELOPMENT OF THE GUT FLORA

B.S. Drasar, University of London, London School of Hygiene & Tropical Medicine, Dept. of Medical Microbiology, *Keppel St., London WC1E 7HT, England, United Kingdom*

Studies in which the diet of individual adults has been changed, have failed to demonstrate those alterations in the flora that were expected as a result of comparisons of people in low and high colon cancer risk areas. The role of breast feeding, diet at weaning and environment in the establishment of the adult flora is being examined. The hypothesis being tested predicts that the flora detectable in adult life is the result of early feeding practices and once established is very resistant to change. Thus the metabolic potential of the flora and hence colon cancer risk would be fixed early in life. Breast fed infants and post weaning children in Malumfashi, Nigeria are compared with those in London, United Kingdom. Nutritional and environmental assessments are also being undertaken. Breath methane in children and adults are being evaluated as epidemiological indicators.

BREAST CANCER MORTALITY CHANGES IN A SCREENED POPULATION

B.A. Thomas, Jarvis Breast Screening, *Stoughton Rd., Guildford, Surrey, United Kingdom*

In the Guildford Breast Screening Project, one the British Breast Cancer Screening Trials, some 25,000 women aged 45-65 are being invited to attend screening centers (fixed and mobile) for clinical examination of the breasts and mammography using the Medichrome low radiation dosage system. General practitioner age/sex registers are being used as the basis for the recruitment of all women in the age group. Personal and medical data, particularly obstetric, breast feeding, and hormonal histories, past breast problems and family histories of breast cancer are being obtained from each woman. These invitations will be repeated two-yearly from updated registers with clinical examination only, carried out by a specially trained nurse, undertaken in the intermediate years. The doctors carrying out the main screening examinations will also read the mammograms, which will be classified according to Wolfe's duct patterns with a view to the determination of mammographic high risk groups. Prevalent, incident and interval cancers will be studied and long-term follow-up undertaken. Mortality rates in this district will be compared with those in other trial and control districts.

THE INFLUENCE OF HORMONE REPLACEMENT THERAPY ON THE INCIDENCE OF BREAST CANCER IN WOMEN

A.M. Stark, Queen Elizabeth Hospital, Dept. of Gynaecological Oncology, *Gateshead NE9 6SX, Tyne & Wear, United Kingdom*

The demand by women for hormone replacement therapy is increasing. Breast cancer is acknowledged to be hormone-dependent. This is a long-term project to assess the influence of hormone replacement therapy on the incidence of breast cancer in women. A cohort of 300 women is being screened for breast cancer by clinical examination, thermography and mammography before commencing hormone replacement therapy and re-examined at three months and annually thereafter. The control group consists of 300 women matched for age, parity, hormonal status, and family history of breast cancer.

HIGH INCIDENCE OF CATTLE CANCER - POSSIBLE INTERACTION BETWEEN ENVIRONMENTAL CARCINOGEN AND PAPILLOMA VIRUS

W.F. Jarrett, University of Glasgow, School of Veterinary Medicine, Dept. of Veterinary Pathology, *Bearsden Rd., Bearsden, Glasgow G61 1QH Scotland, United Kingdom*

The objective is to study the possible co-carcinogenic effects of papilloma virus and bracken fern in inducing alimentary cancer and urinary bladder tumours in cattle. High incidence areas in the upland beef farms of Britain have been demonstrated and the overall incidence in beef cows appears to be of the order of 2.5 to 5 percent per year. high percentage of these animals have pre-existing multiple alimentary papillomas. Virus has been extracted, purified and transmitted from these. An epidemiological study of the farms is in progress to elucidate the latent periods for papilloma induction and to attempt to clarify the sequential stages of cancer development. The relationship between these cancers and human cancers is being examined to determine whether an increased risk is observed in affected farms.

EPIDEMIOLOGY OF BLADDER CANCER IN WEST YORKSHIRE

R.A. Cartwright, Yorkshire Regional Cancer Org., *Leeds LS16 6QB, England, United Kingdom*

Yorkshire has one of the highest mortality rates in the United Kingdom for bladder cancer with an SMR for males in 1969-73 of 114. Incidence and mortality are unevenly distributed within the area and the aim of the project is to account for the high mortality and the variation in incidence. The study is a case-control investigation of prevalent and incident cases for certain hospital areas within the Yorkshire area, including Bradford and Kirklees. The controls are neighbourhood and hospital in type. A questionnaire has been constructed which explores personal habits, past medical history and occupational history in depth. Details of the natural history of the bladder cancer are also recorded. The first phase of the study, dealing with prevalent cases, will be complete in 1979, whilst the incidence study will continue for some years beyond that date. It is hoped that at least 600 cases will be interviewed in the first phase of the study.

AGE-TIME-COHORT ANALYSES OF MORTALITY

J.C. Barrett, University of London, London School of Hygiene & Tropical Medicine, Dept. of Medical Statistics & Epidemiology, *Keppel St., London WC1E 7HT, England, United Kingdom*

This method of mortality analysis was first described in J. Hygiene (Camb.) 71, 253-59, 1973. It consists of the simultaneous use of age, time and cohort factors. Of the three factors, age at death, epoch of death and epoch of birth, one seems almost superfluous. It is nevertheless worthwhile to include all three, allowing for the constraints that the redundancy imposes. This procedure is being applied to published data for England and Wales on breast cancer, bladder cancer and prostate cancer mortality, 1951-1970.

NATIONAL REGISTRATION OF CHILDREN WITH RETINOBLASTOMA IN JAPAN

K. Minoda, University of Tokyo, Branch Hospital, Dept. of Ophthalmology, *3-28-6 Mejirodai, Bunkyo-ku, Tokyo 112, Tokyo, Japan*

Retinoblastoma is the most common intraocular malignant tumor in Japan. To investigate epidemiology, genetics, pathology and clinical aspects of retinoblastoma in Japan, the national registration of retinoblastoma children in Japan was started in 1975 by the Committee for National Registration of Retinoblastoma Children, consisting of 44 ophthalmologists and three other scientists. Interim reports have appeared in Acta Soc. Opthalmol. Jpn. 80: 1648, 1976, and in the proceedings of the International Symposium on Retinoblastoma, Jpn. Opthalmol. 22, No. 3, 1978.

A RETROSPECTIVE COHORT STUDY ON MALIGNANT NEOPLASMS IN WORKERS OF A CHROMATE MANUFACTURING PLANT IN TOKYO

T. Okubo, Jichi Medical School, Dept. of Environmental Health, *3311-1 Yakushiji, Minawi-kawachi-machi, Tochigi-ken 32904, Japan*

The plant chosen for study is the larger of the two chromate manufacturing plants in Japan. In recent years, 24 lung cancer cases have been reported among the chromate workers of the plant. Since the plant was in continuous operation during the period 1915-1975, the follow-up period of over 50 years is longer than that of previous reports. Various types of personnel records as well as payrolls were used to create the cohort; follow-up is carried out by the Japanese family registration system 'koseki'. Measurements of the working environment have been conducted in the plant since 1958, and it is expected that this study will show clearly any dose-response relationship.

OCCULT THYROID CARCINOMA IN TSU, JAPAN

R. Yatani, Mie University, School of Medicine, Dept. of Pathology, *2-174 Edobashi, Torii-Cho, Tsu, Japan*

There is considerable variation in the reported prevalence of occult thyroid carcinomas. At autopsy, the prevalence in the continental United States varies from 0.45%-5.7%. In the native Japanese living in Hawaii it is 24% and in the native Japanese in Japan 17.9%. This variation may be due to the lack of standardized methods of examination and diagnostic criteria. In this study, all available thyroid glands from subjects over age 40 in Tsu autopsied from 1977 to 1986 will be examined, using the criteria and methods of Fukunaga et al. (Cancer 36 (3): 1095-9, 1975), to determine the relative prevalence of such carcinomas and to compare the results with the studies in Canada, Poland, Colombia, Hawaii and southern and northeastern Japan. Each thyroid will be weighed, measured, and sectioned sagittally at 2-3 mm intervals. From each tissue block a routine H- and E-stained section will be prepared for histological study.

MORTALITY STUDY OF ASBESTOS FRICTION WORKERS

M.L. Newhouse, University of London, London School of Hygiene & Tropical Medicine, T.U.C. Centenary Inst. of Occupational Health, *Keppel St., London WC1E 7HT, England, United Kingdom*

This is an old, established plant chiefly devoted to the manufacture of brake linings. Apart from two periods of approximately two years each, more than 30 years ago, only chrysotile asbestos has been used. Identification data of current and past employees is available. With the assistence of the National Register the vital status of past employees will be established and the cause of death, as stated on the death certificate, ascertained. Mortality in this population will be compared with that of the population of England and Wales. Dust estimates are available only since 1969 but by means of simulation experiments dust exposure at various times will be estimated and a case-control study of deaths from lung cancer will be undertaken following the methods of Liddel and Macdonald. Tracing has now been completed and the vital status of approximately 98% of past employees established. Approximately 20% of the 13,000 past employees are deceased and the causes of death established.

YOUNG PATIENTS WITH UTERINE CANCER

K. Masubuchi, Cancer Inst. Hospital, Dept. of Gynaecology, *1-37-1 Kamiikebukuro, Toshima-ku, Tokyo 170, Tokyo, Japan* (01500)

A total of 6,336 cases of cervical cancer were treated in this clinic in the period of 1949-1977. Juvenile

cervical cancer accounted for 886 (13.75) of the cases. Of these 53% were diagnosed as being stage I, and 7.4% were diagnosed as being cervical adenocarcinoma. There were 12 unmarried females and on of them was a virgin. Patients who married before the age of 19 accounted for 22% of the cases, which was found to be significantly higher than the figure for the controls. The percentage of patients who complained mainly of bleeding was 78%. 7% showed no symptom. The five-year survival rate for juvenile cervical cancer was not found to be low. During the 30 years 1949 to 1978 491 cases of endometrial carcinoma were also treated in the clinic. Juvenile corpus cancer was observed in 18 cases whose age was less that 39, the lowest age being 26. In comparing these cases of corpus cancers in ages over 40, the rate of nulliparae in the juvenile cases was as high as 78%. Also, the rate of the cases complaining of menstrual disorder and pain was as high as 61%. There was no tendency of lower survival rate over five years in the cases of juvenile corpus cancers as compared with older cases.

CANCER AND THE INDUSTRIAL ENVIRONMENT

O.L. Lloyd, University of Dundee, Ninewells Medical School, Dept. of Community & Occupational Medicine, *Dundee DD1 9SY, Scotland, United Kingdom*

Environmental influences, many of them industrial, have been held to be responsible for the vast majority of human cancers. This study aims to analyze the patterns of mortality within relatively small populations in Scotland to identify areas where the incidence (or mortality) of specified cancers is abnormally high. It is intended to investigate the environment of these areas in order to try and identify possible carcinogenic factors. It is hoped that the occupational experience of the deceased can be evaluated in order to determine whether or not carcinogenic factors were in the occupational environment or in the more general environment. Evaluation of the environment will be assisted by the collaboration of the Scottish Occupational and Environmental Health Service, Ninewells Medical School, Dundee.

STUDIES ON THE ETIOLOGY OF CHILDHOOD TUMORS

H.B. Marsden, University Hospital of South Manchester, Dept. of Epidemiology & Social Research, *W. Didsbury, Manchester M20 8LR, England, United Kingdom*

This is a population-based study on the incidence of childhood malignancy. Details of all cases of malignancy occurring in the child (0-14 years) population (approximately 1 million) in the North West Regional Health Authority have been collected since 1954. Clinical records and microscopic slides are retained for study. Time-space clustering analysis is being carried out. Factors which may be of etiological significance in childhood malignancy, with emphasis on genetic and environmental aspects, including drugs in pregnancy and parental occupation, are being investigated. A detailed study of family histories is being made with particular emphasis on congenital malformations and malignancies in family members. The quality of life in long-term survivors is being assessed.

COMPLETENESS OF CANCER REGISTRATION

I. Leck, Christie Hospital & Holt Radium Inst., Regional Cancer Epidemiology Unit, *Wilmslow Rd., Withington, Manchester M20 9BX, England, United Kingdom*

Since 1972, the data recorded for cancer patients registered with the Regional Cancer Epidemiology Unit in Mancester (covering a population of over 4 million) have included first treating hospital, hospital to which referred (if any), and dates of registration as well as of first treatment and death. Various possible measures of completeness of registration are being developed and applied to these data, including: 1) Proportion of cases registered by first treating hospital among those registered by hospital to which referred; 2) Ratio of number of cases actually registered to an estimate of the total number diagnosed, calculated on the assumption that the proportion of cases diagnosed in survivors, that is not registered, is the same as the proportion of deceased cases that is only registered because of death. Several methods of estimating the later proportion are being evaluated.

MORTALITY IN CHRYSOTILE ASBESTOS TEXTILE WORKERS - IMPLICATIONS FOR HYGIENE STANDARDS

J. Peto, Imperial Cancer Research Fund, Cancer Epidemiology Unit, *9 Keble Rd., Oxford OX1 3QG, England, United Kingdom*

The eventual risk of developing mesothelioma, lung cancer or asbestosis at the current asbestos hygiene standard (2 fibers/ml in the UK) is not known. Dust levels were rarely measured more than 20 years ago, and more recent exposure has not yet caused a detectable excess of cancer. Dust measurements have been made routinely in this factory since 1951, however, and levels from 1933 to 1950 have been estimated. The principal objective is the study of dose and time relationships for mesothelioma and lung cancer, so that the eventual effects of low asbestos exposure can be predicted from the observed effects of relatively high exposures. 1,100 workers exposed for 10 or more years are being followed up through factory and national records. In addition, mesotheliomas in 25,000 previous and current employees are being traced by matching employment records with the UK National Mesothelioma Register to relate incidence to level of exposure and period and duration of employment. Employment records of mesothelioma cases and matched controls will be compared to assess the risks associated with particular processes in the factory.

CANCER INCIDENCE AMONG EMPLOYEES IN THE CHEMICAL INDUSTRY

A.O. Ahlbom, Huddinge Sjukhus, *S14186 Huddinge, Sweden*

The aim of the study is to assess the association between chemical exposure at work and leukemia and brain tumors. The study is based on the Swedish Cancer Registry. This was linked to the census of 1960 which included information about occupation. The material consists of cases reported to the Registry during the period 1961 to 1973.

AFLATOXIN AND LIVER CANCER IN SWAZILAND

F.G. Peers, University College of Swaziland, Malkerns Research Station, *P.O. Box 4, Malkerns, Swaziland*

Prior studies in Swaziland in 1971 and 1972 established a correlation between liver cancer and dietary aflatoxins, the exposure and disease incidence varying in four topographical areas (Peers et al., Int. J. Cancer, 17, 167-176, 1976). Since then, extensive efforts have been made by the Grain Storage Unit of the Swaziland Ministry of Agriculture to improve 'on farm' storage and, in particular, to prevent rodent and insect damage. Studies will be made to evaluate how much this improved storage has affected the fungal contamination of dietary staples and hence the dietary aflatoxin exposure and whether this is likely to have a significant effect on the liver cancer incidence. Additional studies will be made to determine the primary sources of the aflatoxin in whole diets, and whether intensive efforts at controlling fungal contamination of dietary staples can be economically effected. Studies will also be made of likely confounding factors, and whether aflatoxins in body fluids can be used as a more direct epidemiological assessment of exposure.

INVESTIGATION OF MORTALITY AND MORBIDITY PATTERNS IN CADMIUM WORKERS IN THE UNITED KINGDOM

G. Kazantzis, University of London, London School of Hygiene & Tropical Medicine, T.U.C. Centenary Inst. of Occupational Health, *Keppel St., London WC1E 7HT, England, United Kingdom*

Cadmium is a metal shown to be carcinogenic in animal experimental studies. Limited observations in man suggest that there may be an increased mortality from cancer of the prostate and of the lung in cadmium workers. The study will, in the first instance, seek to ascertain causes of death in cadmium workers, with particular reference to malignant disease and renal pathology. All persons who have worked with regular exposure to cadmium for a minimum period of one year in selected industries will be included in the study. A retrospective register of cadmium workers from records held by the respective companies will be compiled, and mortality data on this defined population obtained and compared with that of an appropriately matched control group.

SECOND PRIMARIES POSSIBLY ASSOCIATED WITH CIGARETTE SMOKING

S. Dische, Mount Vernon Hospital, Regional Radiotherapy Centre, *Northwood HA6 2RN, England, United Kingdom*

A series of patients with bladder cancer have been treated using radio-sensitizing methods. Ninety-six percent of the males have a history of cigarette smoking. These patients are followed with special care to determine the frequency of other diseases. Carcinoma of the bronchus has been the most frequent cause of death other than carcinoma of the bladder. The experience of the general population is used for comparison purposes.

LONG-TERM SURVEILLANCE OF MORTALITY AND CANCER INCIDENCE IN WOMEN RECEIVING HORMONE REPLACEMENT THERAPY (HRT)

S.A. Adam, University of Oxford, Dept. of Social & Community Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom*

In the proposed investigation women seen at 20 menopause clinics in different parts of the country who (1) are currently using HRT and have been using it continuously for at least one year, or (2) are no longer using HRT, but used it in the past for six months or less, will be recruited and followed up indefinitely using the facilities of the National Health Service Registries. Mortality rates and cancer incidence rates of the short-term and long-term users of HRT will be computed from time to time and comparisons will be made with national mortality and cancer incidence data. Cancer of the endometrium and cancer of the breast are sites of particular interest, as well as cardiovascular disease. It is hoped to recruit around 10,000 women over the next three years for the study. So far 1,544 'long-term' users and 234 'short-term' users have been recruited.

ETIOLOGICAL FACTORS IN MALIGNANT MELANOMA OF THE SKIN

S.A. Adam, University of Oxford, Dept. of Social & Community Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom*

A case-control study is being conducted to investigate the role of light, genetic factors, and certain drugs, including oral contraceptives, in the etiology of melanoma of the skin. Cases among women under 50 years of age are to be identified through cancer registries, hospital discharge records, and death certificates. The general practitioner of the case will be interviewed and three controls, matched for age, sex, and marital status, will be selected from his records. All cases and controls will be sent a postal questionnaire.

STUDY OF THE RELATIONSHIP IN INDIVIDUALS BETWEEN CERTAIN CANCERS AND OTHER DISEASES

J.A. Baldwin, University of Oxford, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom*

The files of linked medical records of the Oxford Record Linkage Study, covering an 8-year period, are being analyzed to ascertain whether persons with certain cancers are at increased risk of having or having had other diseases or disorders. Expected numbers are computed after standardization for variables such as age, sex, period at risk, variation with time and migration out of the area. It is hoped that the study will be able both to identify events or long-standing diseases which might be associated with subsequent malignancy and to ascertain conditions which by their association with the cancer might be considered as having a common etiology with the cancer.

A STUDY OF THE EPIDEMIOLOGY, ENDOCRINOLOGY, PATHOLOGY AND RESPONSE TO ENDROCINE TREATMENT FOR BREAST CANCER IN BRITISH AND JAPANESE WOMEN

J.L. Hayward, Imperial Cancer Research Fund, Breast Unit, *Lincolns Inn Fields, London WC2A 3PX, England, United Kingdom*

Breast cancer is less common in Japan than in the United Kingdom, occurs predominantly in young women and probably carries a better prognosis. To obtain more information this collaborative study has been set up to investigate the epidemiology, endocrinology, pathology and response to endocrine therapy of breast cancer in British and Japanese women. In addition, endocrine function in normal Hawaiian-Japanese women and patients with breast cancer and the pathology of breast tumors in Hawaii are being studied.

EPIDEMIOLOGY OF ORAL SQUAMOUS CELL CARCINOMA

N.W. Johnson, University of London, London Hospital Medical College, Dept. of Oral Pathology, *Turner St., London E1 2AD, England, United Kingdom*

Over 300 cases of oral squamous cell carcinoma treated at the London Hospital Medical College are being analyzed in a case characteristics study which aims to determine high risk groups and to establish what factors affect prognosis (e.g., site, age, sex, etiology, size of lesion at presentation, rate of tumor growth and histopathological category). The study is both retrospective and prospective. A modification of the TNM grading and staging system is being evaluated. Data are analyzed using the statistical package for the social sciences with corrections for age employing both the Peto and Peto method and the Cox method.

EPIDEMIOLOGY OF PRECANCEROUS AND EARLY NEOPLASTIC LESIONS OF THE UTERINE CERVIX AND CORPUS

S. Munteanu, Institutul Oncologic Cluj-Napoca, Dept. of Early Diagnosis of Uterine Cancer, *34-36 Republicii, 3400 Cluj-Napoca, Romania*

The objective is to examine the relationship between age at first sexual intercourse, age at first birth, marital status, number of births before age 19 and other known aetiological and epidemiological factors and cervical and corpus neoplasia. A form containing 38 groups of questions, all coded, is filled in by any patient attending the Colposcopy Early Diagnosis Clinic, an out-patient clinic in the Oncological Institute. The following investigative methods are used: Physical examination, various cytological and biopsy examinations, colposcopy, and a thorough inquiry into sexual activity. These are repeated periodically. About 2,500 patients with various benign and malignant cervical lesions and 300 patients with endometrial carcinoma have been recorded and are involved in a long-term follow-up study.

SCREENING OF HIGH-RISK GROUPS FOR EARLY DETECTION OF PRIMARY LIVER CANCER USING MULTIPLE TUMOR MARKERS

C.J. Oon, University of Singapore, Dept. of Medicine, *Outram Rd., Singapore 3, Singapore*

The high-risk groups consist of members of primary hepatocellular carcinoma (PHC) families who are examined for HLA typing and hepatitis status, normal male Chinese hepatitis B carriers over the age of 40 years, and males and females who are on long-term anabolic estrogen and progesterone therapy. The tumor markers being used are alpha-fetoprotein (by counter-immunoelectrophoresis), alpha-1-antitrypsin, alpha-1-acid glycoprotein I, gamma glutamyl transpeptidase, isocitrate dehydrogenase. Individuals with two or more abnormal tests (with or without a raised AFP) will subsequently be examined radiologically for evidence of small PHC. This is a prospective study involving approximately 9,000 individuals.

CANCER OF THE OESOPHAGUS

D.G. Hamilton, South African Inst. for Medical Research, Dept. of Morbid Anatomy & Histopathology, *Hospital St., P.O. Box 1038, Johannesburg 2000, Transvaal, South Africa*

Cancer of the oesophagus is one of the commonest tumors in African Blacks but it is infrequent in Whites. Recent work indicates that there may be a difference in tissue trace elements between these two population groups and this might affect serum antioxidant activity. The study aims to quantitate trace elements in White and Black patients by analysis of serum, hair and tissues. Trace elements of particular interest are zinc, iron and calcium. A special subgroup of the Black patients are those with cancer of the oesophagus. Atomic absorption spectrophotometry and neutron activation analysis are being used for trace element studies. A technique measuring the ability of serum to inhibit oxidation in brain tissue assesses its antioxidant activity. Possible further developments of this study will be the effects of dietary modification on tissue trace elements and serum antioxidant activity.

OCCUPATIONAL CANCER RISK ESTIMATION IN CHEMICAL INDUSTRY

B. Barhad, Academia de Stiinte Medicale, Inst. of Hygiene & Public Health, Dept. of Occupational Medicine, *Strada Biserica Amzei 29, Bucharest, Romania*

A survey to establish the number of workers exposed to carcinogenic chemicals has been carried out in several large plants in the chemical industry. The data have been correlated with levels and lengths of exposure and cancer morbidity. The study aims to develop better methods of circulating information about workers exposed to carcinogenic substances, taking into account movement of the worker population, retirement and the expansion of the chemical industry, and to apply primary and secondary preventive measures to exposed individuals.

CYTOLOGICAL SCREENING FOR LUNG CANCER USING THE SPUTUM OF WORKERS EXPOSED TO CHROMATES AND ASBESTOS

L. Melinte, Academia de Stiinte Medicale, Inst. of Hygiene & Public Health, Dept. of Occupational Medicine Cytopathology, *Strada Biserica Amzei 29, Bucharest, Romania*

The aim of the study is to monitor workers at high risk and to estimate the method of cytological screening of sputum for the early discovery of lung cancer as well as of the epithelial disorders which may precede the development of a tumor. Biennial cytological screening of sputum collected for three consecutive mornings and kept in fixative solution was carried out. Paraffin was added and the sputum was dyed with HE, PAS and Pearls. Correlations were made with age, sex, smoking habits, pulmonary antecedents, exposure length, exposure levels and pulmonary radiography. First results show that cytological changes such as bronchial squamous metaplasia are directly proportional to length of exposure and smoking habits.

LUNG CANCER MORBIDITY IN WORKERS EXPOSED TO INDUSTRIAL CHEMICALS

R. Maties, Academia de Stiinte Medicale, Inst. of Hygiene & Public Health, Dept. of Occupational Medicine, *Strada Biserica Amzei 29, Bucharest, Romania*

The aim of the study is to evaluate the relation between lung cancer and occupational exposure to chromium salts and asbestos. Parameters of exposure which may have an influence on morbidity levels are identified and the relation of possible risk factors other than occupation (smoking habits, residence, previous morbidity) to lung cancer morbidity examined. The project consists of a retrospective study on lung cancer morbidity and mortality among workers exposed to asbestos and bichromates in two plants which have been in operation for more than 30 years, and a prospective follow-up of workers actually exposed. The results of periodical screening (standard chest radiographs, sputum cytology, clinical examination) are recorded and offer a comprehensive description of the changes in the health status.

MALIGNANT TUMORS IN A NATIVE POPULATION UNDER MEDICAL SURVEILLANCE
P.A. Rolon, Registro Nacional de Patologia Tumoral, Dept. of Pathology, *G. Arias y Tte. Rodi, Asuncion, Paraguay*
The relationship between cultural factors, social habits and cancer is being studied in a primitive ethnic group of 10,000 persons under the care of a qualified medical doctor. This population is stable and utilizes hospital service provided by the Mennonite settlers in the Paraguayan Chaco. Relative frequency data for cancer for each five-year age-group will be determined. The information available consists of clinical and laboratory records as well as histopathological diagnosis. The frequency of cancer will be compared with the habits of this population and with data available in the National Registry of Tumour Pathology. It is realized that results could be biased by excess of easily accessible lesions. However, the regular surveillance and the possibility of examining deep-seated organs should reduce such bias.
Description provided by IARC and DKFZ with ICRDB/NCI support.
SUPPORTED BY (No Supporting Organization Reported) funds n.a.

3.1799,
MALIGNANT MELANOMA AND GEOGRAPHICAL SITUATION
P.A. Rolon, Registro Nacional de Patologia Tumoral, Dept. of Pathology, *G. Arias y Tte. Rodi, Asuncion, Paraguay*
The geographical location of the Republic of Paraguay, in the same latitude as South Africa and Australia, permits study of the anatomical localization of malignant melanoma and the relative importance of cultural and racial characteristics. The Tumour Pathology Registry of Paraguay and the Institute of Pathological Anatomy centralize all histologically diagnosed cancers in the country. Previous study of this material concentrated on the frequency of localizing on the sole of the foot, as the habit of walking barefoot is frequent among the rural population. Cases and clinical details from 1960 are in the Institute files and the period 1976-1980 is now being studied.
Description provided by IARC and DKFZ with ICRDB/NCI support.

CERVICAL CANCER EPIDEMIOLOGY IN PANAMA
W.C. Reeves, Gorgas Memorial Lab. of Tropical & Preventive Medicine, Dept. of Virology/Epidemiology, *P.O. Box 2016, Balboa Heights, Canal Zone*
Uterine cervical cancer rates have been increasing in many developing countries. This is particularly marked in the Republic of Panama, which has the highest reported cervical cancer incidence in the world (130/100,000 per year). In addition to this high overall risk, cervival cancer clusters in one province and invasive disease involve an unusually young age cohort. This study aims to identify and evaluate the risk factors associated with the disease in Panama. All hospital and clinic charts from cervical cancer cases treated in all hospitals in Panama between 1974-1979 are being reviewed and key epidemiological information and clinical data are abstracted onto a standardized cancer registry form. This information will be used to define and describe the marked geographical clustering consistently observed in Panama. Results from this initial analysis may be used to augment or modify a case-control study to be conducted in Herrera Province.. The case-control study will collect detailed epidemiological infomation and sera from all surviving cervical cancer cases diagnosed between 1974-1977 and neighborhood/age-matched controls. The information will be gathered and used to test the association of past herpes group virus infection, prior sexual practices, patient drug exposure (including in-utero), geographical and other factors with the occurrence of cervical cancer. It is anticipated that all cases will be registered by March, 1980 and that the field work will begin at that time.
Description provided by IARC and DKFZ with ICRDB/NCI support.

3.1801,
POPULATION-BASED PANAMANIAN NATIONAL CANCER REGISTRY
W.C. Reeves, Gorgas Memorial Lab. of Tropical & Preventive Medicine, Dept. of Virology/Epidemiology, *P.O. Box 2016, Balboa Heights, Canal Zone*
Cancer has been recognized as one of the three principal causes of death in Panama since 1968. In recognition of this, Panama initiated National Cancer Registry in 1974. This existing registry records all histologically diagnosed cancers in the Republic by annually reviewing all tissue diagnoses from medical facilities which operate pathology services. The registry includes only minimal clinical/epidemiological information which is recorded on index cards. This study intends to convert the current National Cancer Registry into an internationally standardized format and to maintain the registry on a computer system. Hospital and/or clinic charts from all patients with diagnosed cancer between 1973-1979 are currently being reviewed, abstracted and put into the standardized format. Clinical data obtained from charts of patients diagnosed after 1977 will be recorded immediately in the registry. The standardized registry includes all the information recommended in the WHO Handbook for Standardized Cancer Registry as core data, most of the information recommended as optional data, and additional locally important information. Information from registry forms is punched on cards for computer-based storage and data processing. The computer system currently in operation is the Conversational Computer Statistical system developed at the University of Washington, Seattle. Such conversation will allow a detailed epidemiological description of cancer incidence throughout the Republic of Panama. It is specifically intended to investigate the etiology of uterine cervical cancer, which has an inordinately high incidence in Panama. It is anticipated that all cervical cancers will be registered by March, 1980. It is also hoped to have registered all cancers of the head and neck, and all female genital cancers including breast by April or May, 1980.

INCIDENCE OF PRIMARY CARCINOMA OF THE LIVER IN METROPOLITAN MANILA
J. Baltazar, University of the Philippines, Inst. of Public Health, Dept. of Epidemiology & Biostatistics, *625 Pedro Gil St., Ermite, Manila, Philippines*
The marked international variation in the incidence of primary liver cancer probably indicates environmental differences in the population-at-risk. In the Philippines, although autopsy studies had suggested a higher frequency of liver cancer compared to other tumors, incidence data are not available. This population-based study aims to describe the incidence pattern of the disease in a metropolitan area where medical facilities are adequate. From the records of the Central Tumor Registry of the Philippines and from death certificates primary liver cancer cases which were diagnosed during a two-year period, 1975-1976, and which were residents of the study area will be identified. The minimum criterion for diagnosis is clinical evidence of the disease. Overall disease rates as well as those specific for age, sex and administrative subdivisions within the study area will be estimated.

ANALYSIS OF NORWEGIAN DIETARY SURVEY DATA
E. Bjelke, Universitetet i Bergen, Inst. of Hygiene & Social Medicine, *5016 Bergen, Norway*
The aim of the study is to examine data on diet, alcohol intake, chewing of tobacco or use of snuff, and data on height and weight to assess the relationships of these factors to subsequent cancer incidence and mortality. Data obtained on other variables, such as place of residence, smoking and physical activity will be considered in the analysis. In this on-going prospective study in Norway, about 1,000 new cancer cases among men are now available for diet-cancer analyses. About 1,000 additional cancer cases in females are available for the height/weight analyses. These analyses are part of a larger project, encompassing case-control studies on diet and gastrointestinal cancer carried out previously, other analyses of the prospective study data, and a parellel prospective study in the USA.

NORTHERN BREAST GROUP - BREAST CANCER SURVEY
R.G. Kay, Auckland University, School of Medicine, Dept. of Surgery, *P.O. Box 2175, Auckland, New Zealand*
The purpose of the study is to study the epidemiology of breast cancer in a multi-racial society in New Zealand. This comparison of case characteristics is both between races and within a race. The controls for the latter are 1,000 women attending general practices in Auckland, New Zealand. They will be matched by age and locality with the breast cancer cases. An average of 260 new cases of breast cancer per annum occur in Auckland. Importance is attached to socio-economic groups, height-weight ratios, diet, parity, history of contraceptive practices and previous breast disease. High risk families in Caucasian and Polynesian communities are under review.

POPULATION SCREENING FOR CERVICAL CANCER
P.G. Voojs, Katholieke Universiteit Nijmegen, Lab. of Cytopathology, Dept. of Pathology, *Geert Grooteplein Zuid 24, Nijmegen, Netherlands* (01507)
Cytological screening of the uterine cervix has proved to be a reliable method for detection of early cervical cancer. The degree of acceptance and effectiveness of such a screening program in the Dutch female population is still unknown. To investigate this question, 3 test regions have been created in the Netherlands. One of these is the region around the city of Nijmegen, where women in the age group of 35-54 years are screened every 3 years. The first screening, examining a total of 72,500 women, was done between 1976 and 1979. A second 3-year period will start in August 1979. The accuracy of cytodiagnosis, acceptance of the screening test by the female population, reasons for non-participation and efficacy of organizational procedures are examined. In a long-term follow-up the effects on morbidity and mortality will be calculated.

In the whole area (300,000 inhabitants) cervical cancer morbidity is registered. A report of the results of the screening in the first three year period, in the three test regions was published in 1980.

ESOPHAGUS CANCER IN KENYA

A. Wasunna, University of Nairobi, Dept. of Surgery, *P.O. Box 30197, Nairobi, Kenya*

This is a study of case characteristics of carcinoma of the esophagus in Kenya. It is a collaborative project including the Department of Surgery and Pathology, University of Nairobi. Data are collected from all patients with esophageal cancer in Kenyatta National Hospital, Nairobi, and in the provincial hospitals of Kisumu, Western Kenya, and Nyeri in Central Kenya, where the disease appears to be especially frequent. Questionnaires are administered to all histologically confirmed cases. A standard protocol suitable for computer analysis is being used in the study. In the last 12 months 60 new cases of the disease have been documented at the Kenyatta National Hospital alone. There is now clinical follow-up data on 550 patients at the Kenyatta National Hospital.

CARCINOMA ARISING IN THE STUMP; STATUS AFTER RESECTION OF THE STOMACH

K. Welvaart, State University Hospital, Dept. of Surgical Oncology, *Wassenaarsweg, Leyden, Netherlands*

An increasing incidence of gastric carcinoma following operation for benign ulcer disease has been reported. The probability of cancer developing in a gastric remnant has been stated to be as high as 10%, especially when a Billroth II reconstruction was performed. It is presumed that the constant reflux of bile and pancreatic juice is related to the cause of this cancer. The aim of this study is to assess the incidence of stump carcinoma, using patient records over the last 20 years, and to examine treatment results and survival. Billroth II procedures have been performed for many years in the State Hospital of Leyden, Netherlands, therefore adequate information should be available for examination.

NUTRITION AND CANCER OF THE COLON - A CASE-CONTROL STUDY IN SPECIFIC GEOGRAPHIC REGIONS OF THE NETHERLANDS

P.F. De Guchteneire, Inst. of Social Oncology, *Dr. Molewaterplein 50, Postbus 1738, 3000 DR Rotterdam, Netherlands*

Mortality rates for cancer of the colon have been increasing in the Netherlands, as in most Western countries. The standardized mortality rates for colon cancer have been reviewed for the different regions of Holland, and an excess mortality was found in the southern part of the country as compared to the northern part. Dietary differences between the northern and southern provinces could in part be responsible for this variation. A study has been designed to investigate in selected geographic regions the role of nutrition in the causation of cancer of the colon. Nutrient intake data from newly diagnosed colon cancer patients obtained by means of a dietary history questionnaire will be compared to that obtained from hospital and population controls. The effect of socio-economic factors on dietary habits is taken into consideration. Microbiological and biochemical investigations are being considered. A pilot study has been completed.

Description provided by IARC and DKFZ with ICRDB/NCI support.

DISTRIBUTION OF SITE-SPECIFIC CANCER MORTALITY IN THE NETHERLANDS

P.F. De Guchteneire, Inst. of Social Oncology, *Dr. Molewaterplein 50, Postbus 1738, 3000 DR Rotterdam, Netherlands*

The objective of the study is to utilize mortality figures to define geographical variations in cancer mortality within the Netherlands. Mortality rates will be standardized for age and sex. Probability testing will be done to assess the significance of high and low mortality rates. The country has been divided into 80 units to make it possible to control for different socio-economic factors. A graphic representation in maps will be made automatically. Computer programs are being developed.

PRENATAL EVENTS AND CANCER RISK IN THE OFFSPRING

D. Dukkers van Emden, Universiteit van Amsterdam, Dept. of Neonatology, *Spui 21, Amsterdam, Netherlands*

The objective is to examine the relationship between use of anti-epileptic drugs or viral infection during pregnancy and cancer risk in the offspring. A follow-up study has been done of the outcome of 249 pregnancies in epileptic women undergoing treatment with anticonvulsants. The children were born between 1963 and 1977. Three children were stillborn, nine died subsequently. Postmortem examination in six cases showed multiple congenital abnormalities, no signs of malignancy. In the remaining group of 237 children, one boy, born in 1966, developed Hodgkin's disease (stage I) in 1973. His mother had used phenytoin, phenobarbital and primidone in high dosages during the entire pregnancy. No other malignancies were found in the group.

MASS SURVEYS OF TOKYO METROPOLITAN GOVERNMENT EMPLOYEES BY X-RAY AND IN HIGH RISK CASES BY SPUTUM CYTOLOGY

Y. Hayata, Tokyo Medical College Hospital, Dept. of Surgery, *6-7-1 Nishishinjuku, Shinjuku-ku, Tokyo 160, Tokyo, Japan*

The aim is to detect lung cancer, hopefully at an early stage. Chest X-rays have been performed since 1953 on employees of the Tokyo Metropolitan Government, and 1,975 lung cancer cases have been detected among a total of 1,717,385 examinees. The overall detection rate per 100,000 was 10.2, 26.6 in males 40 years and over and 9.7 in females 40 years and over. Among these 31.8 percent were stage I, 12.5 percent stage II and 55.7 percent stage III. Resectability rates were 87.6 percent, 82.4 percent and 25.5 percent, and five-year survival rates were 62.2 percent, 28.0 percent and 6.9 percent respectively. There are currently three groups of examinees: a high risk group examined twice year, a group examined annually and a group of cases which was not examined the previous year. The rate of early stage lung cancer detection was 33.3 percent in the semi-annual group, 11.7 percent in the annual group and 7.1 percent in the third group. There were also significant differences between the three groups in resectability and five-year survival rates. Since 1974 sputum cytology surveys have been conducted in a high risk group of 1,295 examinees to detect cancer and atypical squamous metaplasia cells, and cases with squamous metaplasia cells are followed up at four month intervals. Metaplastic cells are examined for DNA-content. Evaluation of squamous metaplasia cells and/or DNA analysis results were based on serial findings in several canine experimental series, in which lung cancer was induced in the major bronchi by intramucosal administration of 20-methylcholanthrene. The work continues. The high risk group is defined as those with a cigarette index of over 400, aged 45 or more, those involved in occupations involving exposure to pollution, and those with cough or bloody sputum.

RADIATION-INDUCED MALIGNANCIES DUE TO MASS SURVEY OF THE STOMACH

M. Sakka, Tohoku University, School of Medicine, Dept. of Radiation Research, *4-12 Hirosemachi, Sendai 980, Miyagi, Japan*

Mass X-ray for detection of cancer of the stomach has been widely used in Japan. The study aims to estimate possible risk due to such low level diagnostic exposures. An exposed population with more than 5 million man-years is registered at the Cancer Detection Center, Miyagi Cancer Society, Miyagi Prefecture. Statistical analysis of the exposed population and dosimetry of every individual will be undertaken and the prospective risk of subsequent malignancies will be estimated in rem per man. The non-exposed population of Miyagi Prefecture will be used as control population.

EPIDEMIOLOGY OF NASOPHARYNGEAL CARCINOMA IN JAPAN

S. Sawaki, Yokohama City University, School of Medicine, Dept. of Otolaryngology, *3-46 Urafune, Minami-Ku, Yokohama 232, Kanagawa Ken, Japan*

The incidence of nasopharyngeal carcinoma is highest in the populations of Southern China, while in Japanese it is very low. This descriptive epidemiological study of nasopharyngeal carcinoma in Japan aims to discover the reason for this difference. The nasopharyngeal carcinoma cases, observed in the major hospitals of the whole of Japan are reported to this laboratory each year. Age and sex distributions, geographical variation and ethnic background will be examined. Histological sub-classifications of the reported cases are being made, and relationships to Epstein-Barr virus infection (anti-VCA-antibody titers, etc.) examined.

ESTIMATION OF PREVALENCE OF CANCER IN JAPAN

K. Aoki, Nagoya University, School of Medicine, Dept. of Preventive Medicine, *65 Tsurumai-cho, Showa-ku, Nagoya 466, Aichi ken, Japan*

A one day nation-wide survey of all patients of all hospitals (835) and 1/100 of all dispensaries (734) randomly selected throughout Japan was conducted in 1976. A one month survey of all patients discharged from the same medical facilities in June was carried out at the same time. A total number of 264,945 patients, excluding those reported from dental clinics, was reported in the one-day survey. This total included 7,397 cancer patients. To estimate the prevalence of cancer by site, the reported

numbers were corrected by the sampling ratios, by treatment status, in- or out-patients, and also by the average daily number of patients for a week. The interval of attendance at the clinics was also used for correcting the prevalence for the out-patients. The first visit patients were excluded from the estimation of prevalence. The estimated number of cancer patients of all sites was 278,910 (crude rate per 100,000: 248.1 for both sexes, 211.1 for males and 282.1 for females). The ratio of the estimated prevalent cases to that of the deaths from cancer of all sites in 1976 was 1.7 for male and 3.1 for females. The estimated number of stomach cancer patients was 52,900 (crude rate 95 per 100,000) for males and 33,700 (crude rate 59 per 100,000) for females and the ratio of the prevalent cases/death was 1.7 for males and females. The 1977 survey will be examined.

CASE-CONTROL STUDY OF ESOPHAGEAL CANCER

K. Aoki, Nagoya University, School of Medicine, Dept. of Preventive Medicine, *65 Tsurumai-cho, Showa-ku, Nagoya 466, Aichi ken, Japan*

A high death rate for esophageal cancer has been recorded in Wakayama Prefecture, where some dietary factors are suspected as carcinogenic agents. Aichi Prefecture has had low death rates for the same three decades. The purpose of this case-control study is to clarify the role of dietary factors, such as hot tea gruel, bracken-fern and others, and also of socio-economic factors in features between patients in Wakayama and Aichi will be compared. 150 cases of esophageal cancer and 300 controls in Aichi and 100 cases and 200 controls in Wakayama will be interviewed. Cases are the patients admitted into major hospitals in Nagoya and Wakayama cities. Controls are selected from all patients admitted to the same hospitals, matched for age, sex, residence, and date of admission. Preliminary results on 100 controls show that esophageal cancer patients had a high intake of pork and chicken treated with soy sauce, salted foods, tea gruel and alcohol in Wakayama, and a high intake of pork, a light breakfast such as bread and tea or coffee and Japanese noodles in Aichi. The risk-reducing factors include a high intake of tomatoes, fruit juice, peaches and bean sprouts in Wakayama, and of cabbage, medicated wine and coca-cola in Aichi. Esophageal cancer appears to occur more commonly in low socio-economic groups in Wakayama, and in nutritionally deficient groups in Aichi. The common risk factor in both areas is smoking.

GEOGRAPHICAL VARIATIONS AND TIME TRENDS OF CANCER MORTALITY IN JAPAN

T. Kuroishi, Aichi Cancer Center Research Inst., Division of Epidemiology, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan*

Mortality from some malignant neoplasms in Japan shows marked variations in geographical distribution and secular trends. This study aims to describe mortality from cancers of 18 sites for each prefecture and smaller administrative districts in Japan (1969-1976) and to find possible cancer risk factors by examining geographical and chronological relationships between mortality from cancers of various sites and various environmental factors, such as air pollution, food intake, smoking, socioeconomic factors, etc.

ANALYSES OF GEOGRAPHICAL VARIATIONS AND TIME TRENDS OF MORTALITY FROM MALIGNANT LYMPHOMAS IN JAPAN

H. Shimizu, Aichi Cancer Center Research Inst., Division of Epidemiology, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan*

The aim of this study is to discover etiological factors in malignant lymphoma. As a first stage the geographical distribution of mortality from reticulum-cell sarcoma, lymphosarcoma, Hodgkin's disease and other neoplasms of the lymphoid tissue was generally high in the south-western parts of Japan for both sexes in 1969-1976. The geographical distribution of malignant lymphoma was similar to that of lymphatic leukemia in the same period in Japan. The mortality rate of Hodgkin's disease has been calculated for each city and town in two prefectures with a high mortality and several clusters were found in districts around a bay or in small islands in southern parts of Japan. It is considered that these malignancies of the lymphatic and hematopoietic tissue might be caused by similar agents. Pathological information has been collected from Japan Autopsy Reports and this will be analyzed to explore causal factors of the disease. It is also planned to collect and analyze the medical records of malignant lymphoma patients in the Aichi Cancer Center Hospital.

LUNG CANCER MORTALITY AND AUTOMOBILE EMISSIONS

H. Shimizu, Aichi Cancer Center Research Inst., Division of Epidemiology, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan*

To examine the causal association between exposure to vehicular emissions and lung cancer, the mortality rates for lung cancer (1969-1974) were analyzed among inhabitants living in the areas within 100 meters from main streets on which more than 1,000 cars pass daily from am to 7 pm in Nagoya city. Traffic volume was regarded as an indicator of the degree of exposure to exhaust gas. The preliminary results show an increase in the standardized mortality ratio (SMR) of lung cancer in parallel with the traffic volume for males. However, for females the SMR was highest in the intermediate areas and did not parallel the traffic volume. No apparent relationships were observed between proximity to streets and lung cancer mortality. Mortality adjusted by smoking history, history of hazardous exposure and residential history showed similar results. The relationship between lung cancer mortality and traffic volume will be analyzed according to the histological type of lung cancer.

RELATIONSHIP BETWEEN AIR POLLUTION AND CANCER IN JAPAN

S. Tominaga, Aichi Cancer Center Research Inst., Division of Epidemiology, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan*

This study aims to clarify the relationship between air pollution and cancer mortality. Sulphur dioxide (SO2) and nitrogen oxide (SO2) levels and dustfall were used as indexes of air pollution. The average value of each pollutant for each of the 46 perfectures (1967-1975) was related to the age-adjusted mortality rates of cancers of the lung, esophagus, stomach, breast and uterus (1975) for the corresponding prefecture. In examining relationships between air pollution and cancer mortality, smoking was also taken into account. The relationship between SO2 and lung cancer and breast in females and those between NO2 and lung cancer in both sexes and breast cancer in females was statistically significant after taking into account the proportion of smokers. Analysis continues.

3.1824,
RELATIONSHIP BETWEEN CANCER MORTALITY AND CONSUMPTION OF FOOD, ALCOHOL AND TOBACCO

H. Ogawa, Aichi Cancer Center Research Inst., Division of Epidemiology, *81 1159 Kanokoden Tashiro-cho, Chikusa-ku, Nagoya 464, Aichi, Japan*

Food, alcohol and tobacco are thought to be the dominant causal agents of cancer. To elucidate the relationship between cancer mortality and the consumption of these elements, the age-adjusted death rates from cancer by sex for 1972, the per capita supply of food and alcohol from 1960-1962 in 27 countries of the world and 46 perfectures of Japan, and the per capita supply of cigarettes in 1965 in Japan were analyzed by factor analysis. Two major factors emerged, one called the 'western-urban' factor and the other the 'alcohol-related' factor. The geographical distributions of these factor scores were also examined. Time trend analyses are now under way.

EPIDEMIOLOGY OF CANCER OF THE MAXILLARY SINUS

T. Hiyama, Center for Adult Diseases, Dept. of Field Research, *3-3 Nakamichi 1-Chome, Higashinari-ku, Osaka 537, Japan*

Cancer of the maxillary sinus is a rare disease, but its incidence in Japan is the highest in the world and 86.9% of these cancer cases diagnosed in Osaka during 1967 and 1977 were epidermoid. A case-control study was performed to study the relationship between maxillary sinus cancer and chronic maxillary sinusitis. 312 cases were observed at the hospitals in Osaka, and 314 matched controls were selected from healthy persons examined at the Center for Adult Diseases. A history and physical signs of the chronic sinusitis, and abnormal x-ray findings were much more frequent among cancer cases than among controls. A follow-up study of patients diagnosed as having chronic maxillary sinusitis is planned. 478 cases have been registered and a further 500 cases will be collected in 1980.

THE LATE RADIATION EFFECTS OF ATOMIC BOMB EXPOSURE IN THE POPULATION OF HIROSHIMA AND NAGASAKI, JAPAN

M. Tamaki, Radiation Effects Research Foundation, *5-2 Hijiyama Pk., Minami-ku, Hiroshima 730, Hiroshima, Japan*

The Atomic Bomb Casualty Commission (ABCC) in Japan was organized in 1947 under the supervision of the U.S. National Academy of Sciences (NAS) to detect late radiation effects in the people of Hiroshima and Nagasaki exposed to the 1945 atomic bombs. In 1975 ABCC was reorganized as the Radiation Effects Research Foundation (REFEF), a private non-profit foundation funded equally by Japan and the United States. The RERF offices, laboratories, and examination facilities are maintained in both Hiroshima and Nagasaki, where adult health examinations, autopsies, clinical research, and epidemi-

ological studies are conducted. The basic population for the epidemiological and autopsy studies numbers about 109,000 survivors and their controls and 54,000 of their children. Biennial clinical examinations are conducted on about 15,000 survivors and their controls in the two cities. A number of important radiation-related clinical disorders and abnormalities have been detected in the atomic bomb survivors, including increased frequency of lenticular opacities, thyroid tumors, leukemia, chromosome aberrations in the peripheral lymphocytes, and slight impairment of growth and development of those exposed in utero, especially if significant exposure occurred during the early period of gestation. Recent findings indicate an increased incidence of solid tumors among the more heavily irradiated survivors most apparent for breast and lung cancers; this may extend to cancer of the stomach and other sites. The RERF plans to continue its health examination, mortality, and autopsy programs. Particular attention in the clinical examination population is now being focused on early cancer detection, cancer education, alteration of immunological competence, and acceleration of aging. The tumor and tissue registry programs in Hiroshima and Nagasaki complement the RERF studies for the detection of radiation-induced tumors.

ANALYSIS OF MASS HEALTH EXAMINATION FOR UTERINE CERVICAL CANCER IN JAPAN

H. Yanagawa, Jichi Medical School, Dept. of Public Health, *3311-1 Yakushiji, Minawi-kawachi-machi, Tochigi-ken 32904, Japan*

The effectiveness of mass health examinations for uterine cervical cancer is being evaluated with the aid of mathematical models based on the standard examination system widely employed in Japan. Epidemiological data such as incidence and prevalence rates of early and later stages, and mortality rates from cervical cancer were collected from 18 local cancer institutions. Evaluation of the mass examination is performed according to the interval between examinations, coverage rate in the population, and selection of high risk populations.

A PROSPECTIVE SURVEY OF CANCER IN LESOTHO 1970-1974

P.M. Martin, University College of Swaziland, *Private Bag, Kwaluseni, Swaziland*

One thousand two hundred twenty-three cases of cancer have been collected between 1970 and 1974. The crude rates and epidemiology of the main cancers (cervix, breast and liver) have been determined with the help of the recently published Lesotho Census of 1976. Analysis of the questionnaires completed by the patients shows that they are more traditional, less educated and poorer than a similar group of healthy controls. Furthermore, cervix cancer patients ingest substantially more fermented porridges and drinks which have been recently shown to contain the mycotoxin zearalenone. A recent publication appeared in S. Afr. J. Sci. 75, 501-511, 1979.

LEUKEMIA IN SUDAN

M.A. Ahmed, University of Khartoum, *P.O. Box 102, Khartoum, Sudan*

Only a few preiminary studies, consisting of small numbers of cases, have been published on the incidence of leukemia in the Sudan. This vast country has unparalleled variations in environment and ethnic backgrounds. The present study aims to assess the incidence of the different types of leukemia by age and sex and their regional distribution within the Sudan and to find out whether there is any association between environmental factors and the incidence of leukemia. A personal history which includes the locality and the patient's tribe is taken for all the leukemia cases seen during the period of the study. These cases are examined by one or more of the study collaborators and clinical diagnosis is made. The latter is confirmed by peripheral blood count and a bone marrow examination which are carried out in the hematology department of the University of Khartoum. Cytochemical staining is used in the controversial cases. The findings are recorded on special cards and at the end of the first part of the study 256 cases have been collected.

MORTALITY EXPERIENCE AMONG POLYCHLORINATED BIPHENYL WORKERS

P.A. Bertazzi, Universita degli Studi di Milano, Inst. of Occupational Health, Dept. of Epidemiology, *Via San Babila 8, 20122 Milan, Italy*

Animal experiment studies and some human data support a possible association between polychlorinated biphenyls (PCBs) exposure and cancer in man. The aim of the study is to assess mortality in the period 1955-1975 among workers employed in a capacitor and transformer industry operating since 1947. The personal records of the 2,317 workers employed since the beginning of manufacture have been obtained from the factory. For each subject date and place of birth, date of entry and leaving the industry and type of work performed are available; date, place, and primary cause of death will be ascertained from death certificates. The sex, age and cause-specific mortality of people living in the same city where the factory is located will be used for comparison.

A FOLLOW-UP STUDY OF LEPROSY PATIENTS

S. Tokudome, Kyushu University, School of Medicine, Dept. of Public Health, *3-1-1 Maidashi, Higashi-ku, Fukuoka City 812, Fukuoka ken, Japan*

It is known that there is a high cell-mediated immune response in tuberculoid leprosy, whereas such a response is absent in lepromatoid leprosy. Recently DDS (diamino-diphenyl-sulfone), which is used to treat leprosy, has been found to be carcinogenic in animal experiments. The aim of this study is to examine the mortality of leprosy patients with special reference to malignant neoplasms. Some 2,000 patients admitted to a leprosarium, from 1956 to 1977, are analyzed by types of the disease and their mortality experience is compared with that of the general population in Japan. The data will also be analyzed in terms of possible carcinogenicity in patients treated with the drug.

EPIDEMIOLOGY OF CHILDHOOD CANCER IN THE PROVINCE OF TORINO, ITALY

G. Pastore, Universita degli Studi di Torino, Clinica Pediatrica, Serv. di Oncologia, *Piazza Polonia 94, c/o Ospedale Regina Margharita, 10126 Turin, Italy*

A special childhood cancer registry (children aged 0-14) for residents in the province of Torino (total population at the time of the 1971 census: 2,287,016, of whom 497,223 were aged 0-14) has been operating since 1965. Cases are recorded according to ICD and histological types. Data for the 1967-74 period have been published (Rivista Italiana di Pediatria 5: 337-345, 1979). The collection of cases and their analysis have been completed for the period 1975-78. Incidence rates are similar to those of other industrialized countries in the Western World. Incidence rates have been calculated for residents in the city of Torino and residents in the rest of the province as well as for different areas within the province. The incidence rate for all cancers and for neurogenic tumors was higher in the city of Torino than in the rest of the province in the period 1967-74, but not between 1975 and 1978. By 1982 collection of cases will be completed for the period up to December 1981. Trends in incidence, mortality and lethality are being investigated, as well as the distribution of cancer in children among the indigenous population as compared to the population immigrating from other parts of Italy.

EPIDEMIOLOGY OF KAPOSI'S SARCOMA IN SARDINIA

D.M. Cerimele, Universita degli Studi di Sassari, Dept. of Dermatology, *Viale Mancini 5, 07100 Sassari, Italy*

The main goal of the present research is to analyze the incidence of Kaposi's sarcoma in Sardinia and to establish whether generalized forms of the disease, like those described in Uganda, are present and to what extent. Kaposi's sarcoma in Sardinia does seem to be more frequent than in other parts of Italy and is certainly more frequent than in the other countries of Europe. The study will investigate the distribution of Kaposi's sarcoma in Sardinia to see if the disease is more common on the coast or in the interior part of the island and if the disease is associated with other diseases such as diabetes, malaria, tuberculosis, Mediterranean anemia, Hodgkin's disease or other lymphomas. An examination of cell-mediated immunity in patients affected by Kaposi's sarcoma has been started to investigate whether there is a correlation between the generalization of the disease and a possible impairment of the cell-mediated immunity.

ENVIRONMENTAL FACTORS AND THE DEVELOPMENT OF SKIN CANCER

D.M. Cerimele, Universita degli Studi di Sassari, Dept. of Dermatology, *Viale Mancini 5, 07100 Sassari, Italy*

There is ample evidence that environmental factors and particularly prolonged exposure to the rays of the sun play a significant role in the development of skin cancer. This study intends to determine the actual incidence of skin cancers in Sardinia, and the degree to which environmental and constitutional factors are involved. A questionnaire, developed for the present study, collects information from skin cancer patients on place of birth, place of residence during last ten years, place of present residence, color of the skin, eyes and hair, capacity to tan and time of exposure to the sun. Patients treated are followed up in order to establish if people who develop skin cancer are prone to develop new cancers of the skin or inner organs in the future.

SURVIVAL OF BREAST CANCER PATIENTS RELATED TO RISK FACTORS

M.K. Purde, Ministry of Health of the Estonian SSR, Inst. Eksper. i Klin. Medit., Dept. of Clinical Oncology, *42 Hiiu St., Tallinn 200016, Estonian S S R, Union of Soviet Soc. Republics*

Survival rates for patients with breast cancer have been reported to be different not only due to the extent of the disease and efficiency of the treatment but also in connection with some other factors. This research is based on 500 breast cancer cases who received initial treatment in the period 1967-1973. The aims of the study are to evaluate the relationship between certain risk and biological factors (family history, age at first birth, age at menarche, some allied diseases, histology) and probability of survival. The surveillance system is introduced by the population-based Estonian Cancer Registry. All the data are being processed by different methods in order to analyze survival experience.

IS ANGIOSARCOMA OF THE LIVER ASSOCIATED WITH VINYL CHLORIDE MONOMER EXPOSURE IN SOUTH AFRICA?

I. Webster, South African Medical Research Council, National Research Inst. for Occupational Diseases, *Joubert St. Ext., P.O. Box 4788, Johannesburg 2000, Transvaal, South Africa*

In South Africa the main producer of polyvinyl chloride plastic has two factories. It has been manufactured at Umbogintwini since 1950, but at the Midlands factory for only eight years. The present labor force is being monitored by liver tests and clinical and radiological examinations. Ex-employees are being traced, especially those from Umbogintwini, in whom, if they were exposed to vinyl chloride monomer, the possible latent period of 20-30 years has now been reached.

INFECTIOUS COMPLICATIONS IN CHILDHOOD LEUKEMIA - A RETROSPECTIVE AND PROSPECTIVE STUDY

P. Lahde, Tampere Yliopisto, Inst. of Clinical Sciences, *PI 607, 33101 Tampere 10, Finland*

Infectious complications in patients under 15 years of age with leukemia or lymphoma treated in Tampere Central Hospital between 1963 and 1979 are being reviewed. The information is being applied for more effective specimen collection and laboratory studies in the prospective part of the study. New patients entering the study are being screened for immunity against various viruses and protozoa. In addition to studies on acute infections, the occurrence of latent cytomegalovirus infection will be followed in the patients by repeated serological testing of CMV early antigen-antibody and by virus isolation. At the same time the patients are being studied for cell-mediated immunity by lymphocyte stimulation and skin testing.

HLA ANTIGENS AND HEPATOCELLULAR CARCINOMA IN GREECE

J. Zervas, University of Athens, School of Medicine, Dept. of Internal Medicine, *Odos Panepistimiou 30, Athens 609, Greece*

Greeks, as it is known, show an increased frequency of hepatocellular carcinoma (HCC) in comparison with other Europeans. This fact caused us to study in our country the possible relationship of this disease with genetic factors and we chose HLA system for study.

Our material consisted of 52 unrelated Greek adults with histologically proven HCC. 54 antisera detecting 27 HLA (A and B) specificities (11 and 16, respectively) were used according to the standard two-stage NIH microlymphocytotoxicity technique. The results were compared with those of 400 unrelated healthy Greek individuals. To evaluate the observed differences between the two groups chi-square analysis with Yates' correction was applied and P values were corrected for the number of comparisons (Pc).

In our material there is a statistically significant deviation of the antigen HLA-B12 (Pc less than 0.015) with a relative risk of 3.23. HLA-A9 also shows a deviation (P less than 0.01, RR equals 0.32) which, however, becomes insignificant when corrected (Pc greater than 0.05).

According to our results it would seem that the antigen HLA-A9 protects from, while the antigen HLA-B12 predisposes towards, the disease. It would be interesting to see whether analogous relationships exist in other populations.

INVESTIGATION OF INFANT AND PRESCHOOL DIETS AND THEIR RELATIONSHIP TO DENTAL HEALTH

G.D. Derkson, University of British Columbia, Faculty of Dentistry, *2075 Wesbrook Pl., Vancouver, British Columbia, Canada* V6T 1W5

PURPOSE: To determine the incidence of nursing bottle syndrome (deep carious lesions in the upper primary incisors and the upper and lower primary first molars) in Vancouver preschool children; and to examine their health and diet histories to determine what factors might correlate with the incidence of the disease.

SUBJECTS: As many preschool children as possible, ages 9 months to 5 years, of either sex, secured from the records of the Vancouver Health Department and child health centers.

METHODS: Mothers consenting to participate will be interviewed as to the health and dietary history of their children in order to complete a detailed questionnaire. The child's teeth will be examined, using a mouth mirror and flashlight, to determine whether or not the child exhibits the typical lesions of nursing bottle caries.

ACCIDENTAL EXPOSURE TO DIMETHOATE AND ITS DERIVATIVES

E.L. Matos, Instituto Oncologia Angel H. Roffo, Dept. of Research, *Av. San Martin 5481, 1417 Buenos Aires, Argentina* (01940)

Contradictory results have been found in experimental animals regarding the carcinogenicity of Dimethoate (positive in Wistar rats, negative in Osborne Mendel rats and B6C3F1 mice). This phosphorate pesticide has proved to be mutagenic within diverse systems and its derivatives are more toxic than demethoate itself. In April 1979, an exothermic reaction occurred in Buenos Aires in a cistern where Dimethoate was being formulated. Gas leakage lasted four hours until the product in the cistern was exhausted. Two persons died and 30 had intoxication symptoms, shown in 76% of the exposed by respiratory or digestive tract or central nervous system symptoms. One month later, smell persistance in 23% and decrease in libido in 35% were striking. Twelve months post-accident all the individuals were asymptomatic.

It is intended to follow up a cohort composed of 25 firemen, who were the most exposed, to date of death.

EPIDEMIOLOGICAL ASPECTS OF VULVAR CARCINOMA IN ISRAELI JEWISH PATIENTS

J. Menczer, Tel Aviv University, Sackler School of Medicine, Dept. of Obstetrics & Gynecology, *c/o Sheba Medical Center, Tel Hashomer 52621, Israel*

While the low incidence of squamous carcinoma of the uterine cervix (SCC) in Jewish women is well known and other epidemiological aspects have been widely studied abroad as well as in Israel, no epidemiological studies of squamous carcinoma of the vulva (SCV) in Jewish women have so far been performed. The purpose of this investigation is to perform a population-based study of SCV in Israeli Jewish women in order to investigate whether epidemiological data with regard to age pattern, relative incidence and ethnic distribution follow data on squamous carcinoma of the uterine cervix in view of the multicentric origin concepts of malignancies of the lower genital tract.

DISTRIBUTION OF COLONIC NEOPLASMS IN TURKEY

F. Memik, Bursa University, Medical School, Dept. of Internal Medicine, *Bursa, Turkey* (02074)

Incomplete data collected from several sources in Turkey indicate that colon cancer occurs more frequently in western regions of the country. This may be due to socio-economic and, in particular, dietary differences between the populations living in high mountain plateaus and coastal areas. Diet in the mountainous regions consists mostly of carbohydrates and starch. On the coast, meat, vegetables and citrus fruits are eaten in greater quantities. Diet in both regions will be studied in relation to incidence figures.

COLLABORATIVE STUDY OF NEOPLASIA AND STEROID CONTRACEPTIVES

B. Modan, Chaim Sheba Medical Center, Dept. of Clinical Epidemiology, *Bitan 27, Tel Hashomer, Ramat Gan, Israel*

This is a collaborative case-control study of malignant neoplasms of the breast, corpus uteri, gallbladder, liver and ovary in relation to oral contraceptives. Approximately 200 cases and double the number of controls are expected to enter the study each year. All study subjects will be interviewed in hospital. The interview schedule contains questions on prior use of oral contraceptives and other methods of contraception, medical history with an emphasis on gynecological and obstetrical history and family medical history. Pathology slides from all cases will be obtained and reviewed by a reference pathologist. This study is also being conducted in Chile, the Philippines, Mexico, Nigeria, Thailand and Australia.

CANCER EPDIEMIOLOGY IN JAPANESE AND THEIR DESCENDANTS RESIDENT IN SAO PAULO

A.P. Mirra, Universidade de Sao Paulo, School of Public Health, Dept. of Epidemiology, *Avenida Dr. Arnaldo, 715-10 A, Sao Paulo, Sao Paulo, Brazil*

Distribution of cancer incidence among the Japanese resident in Japan, the Japanese who have migrated to Sao Paulo, the non-Japanese living in Sao Paulo, and in descendents of Japanese residents in Sao Paulo will be studied and the results compared. Data from the Cancer Registry of Sao Paulo, complemented by interviews, will be used. The period will cover the years 1969-1973. Information will be recorded on age, sex, civil status, occupation, time of residence, primary site of tumor, means of diagnosis, histology, date of migration, food habits. The number of cancer cases in the Japanese and their descendants is estimated to be 1,000 and the duration of the study is two years.

CASE-CONTROL STUDY ON BRAIN TUMORS AND OCCUPATION

M. Musicco, C. Besta Neurological Inst., Dept. of Environmental & Occupational Neuropathology, *Via Celoria n.11, 20133 Milan, Italy* (02033)

The etiology of brain cancer in humans is mostly unknown; a number of chemicals, however, have been shown to induce tumors of the nervous system in animals (mainly nitrosureas), and a few are suspected of inducing human cancer. In this study the exposures of cases and controls are assessed from data on occupational history and specific chemical exposures, obtained by interview. Following preliminary data showing an excess of farmers among cases, specific questions on herbicides and pesticides have been added since November 1980 to the questionnaire. Cases are all patients with a definite diagnosis of glioma or meningioma admitted to this Institute since November 1980 (about 100 cases of glioma and 100 cases of meningioma each year). Two controls for each case are matched by sex, age, and residence.

GENETIC EPIDEMIOLOGY OF BREAST CANCER

M. Murata, National Inst. of Radiological Sciences, Div. of Genetics, *9-1, 4-chome, Anagawa, Chiba-shi 260, Chiba, Japan*

Family studies so far carried out in various countries indicate that the genetic effect on breast cancer is related to age of onset. The present study aims to examine this in Japan and further to investigate what kind of genetically determined trait is responsible and how it is transmitted. The age distribution in about 3,600 breast cancer patients treated at the Cancer Inst. Hospital in Tokyo was studied. Those with a positive family history, especially patients whose mother had had breast cancer, are significantly younger than the average total cases. Preliminary results suggest a tendency, although not statistically significant, to greater body weight and height in these familial cases compared with total cases. Other epidemiological factors, such as fortility, are studied simultaneously.

CORRELATION OF AIR POLLUTION AND CANCER

J.M. Oomen, National Inst. of Public Health, Div. of Epidemiology & Regional Lab., *P.O. Box 1, 3720BA Bilthoven, Netherlands*

In this collaborative project between the International Agency for Research on Cancer and the National Institute for Public Health (RIV) correlation study between air pollution and cancer will be developed, which will exploit the unique automated system of air pollution monitoring existing in the Netherlands. The pollution data collected are such that it is possible to produce an integrated average exposure to sulphur dioxide, the oxides of nitrogen, ozone and carbon monoxide, for a large number of areas covering the entire country. The Netherlands National Vital Statistics Office will be consulted for information on cancer and other death rates, for the areas considered to be meaningful for atmospheric pollution exposures. The Automated Pathological Diagnoses Storage and Retrieval System (PALGA) has an important potential for epidemiological studies as the information about cases of cancer is based on histological diagnoses.

ANTHROPOLOGICAL, FAMILIAL AND PRENATAL FACTORS IN HEMOPOIETIC SYSTEM NEOPLASMS
E. Quiroga Micheo, Grupo Argentino Cooperativo de Estudios Epid. en Hematologia, *Las Heras 1895, 1127 Buenos Aires, Argentina*
Differences in mortality rates for these neoplasms have been observed among the different immigrant groups in Argentina. Preliminary results of a case-control study carried out on 603 case-control pairs show: (1) fewer cases of acute non-lymphocytic leukemia and Hodgkin's disease in Spaniards, and more cases of lymphoproliferative disorders in Spaniards and of Hodgkin's disease in Italians; (2) acute non-lymphocytic leukemia cases had fewer Spanish ancestors and cases of lymphoproliferative disorders had fewer Paraguayan, Chilean and Bolivian ancestors; (3) fewer cases of acute lymphocytic and non-lymphocytic leukemia had green eyes, and among the latter there were fewer people with blue and grey eyes; (4) there were no differences in the proportional mortality caused by cancer or hemopoietic system neoplasms among relatives and spouses; (5) in the cases it was observed that fewer patients were born from young mothers and fewer were first born. The differences were observed both in children and in adults. No differences were observed in other prenatal factors. The study continues.

3.1871,
FREQUENCY OF CHAGAS DISEASE IN CANCEROUS PATIENTS
E. Sacerdote de Lustig, Instituto Oncologia Angel H. Roffo, Dept. of Research, *Av. San Martin 5481, 1417 Buenos Aires, Argentina*
Several authors have demonstrated the oncolytic effect of Trypansoma cruzi, the agent of Chagas disease, on mouse sarcomas and carcinomas. An epidemiological study was designed to study Chagas disease frequency in a group of patients at the Inst. of Oncology Angel H. Roffo in Buenos Aires. Out of 896 patients studied 74 (8.2%) were serologically positive for Chagas, 66.3% of them suffering from malignant tumors and 33.7% with non-cancerous pathologies. Tumor frequency was significantly higher in the Chagasic patients than in the serologically negative ones. When localizations were compared, a higher frequency of esophagus, uterine cervix and urinary system cancers was found in the Chagasic group. The present project is designed to study Chagas disease frequency in a larger group of patients with tumors of the cervix, esophagus and urinary system (bladder and kidney). Sera from patients will be tested by complement fixation, hemoagglutination, latex and immunofluorescence to diagnose Chagas disease. Information on age, anatomopathological diagnosis, place of birth, place of longest residence, cultural and socio-economic level and transfusions will be collected. Approximately 150 patients will be studied.

DIET AND BREAST CANCER
E. Sacerdote de Lustig, Instituto Oncologia Angel H. Roffo, Dept. of Research, *Av. San Martin 5481, 1417 Buenos Aires, Argentina* (01910)
Evidence of the influence of dietary factors in high breast cancer incidence is found in developed countries. Breast cancer is one of the primary causes of death for females in Argentina, and the aim of this study is to determine whether a diet particularly rich in animal proteins and fat can be associated with this high incidence. 150 diagnosed breast cancer patients have been interviewed until now. The required information includes personal data, gynecological and obstetrical history, hormonal treatment and diet, with special emphasis on fat and protein contents. Two control groups are being used, matched by age and sex, one composed of healthy consanguineous relatives, the other of healthy women who have no cancer history.

LUNG CANCER AND AIR POLLUTION IN HAMILTON
D.L. Sackett, McMaster University, Dept. of Clinical Epidemiology & Biostatistics, *1200 Main St. W., Hamilton, Ontario, Canada* L8S 4L8 (02175)
Previous work has shown that crude lung cancer death rates are higher in areas of Hamilton nearer to the major industries, but such factors as age, sex, smoking and socio-economic status were not taken into account. This study will make use of data on air

pollution levels and age-, sex- and socio-economic-specific death rates as well as a survey of smoking habits to examine roughly 600 lung cancer deaths in the city between 1972 and 1976. After allowing for the confounding variables, the relationship between air pollution and lung cancer mortality will be determined.

COMPARATIVE ANALYSIS ON CANCER DEATHS AMONG LOCAL POPULATIONS IN SAITAMA PREFECTURE, JAPAN

T. Sasaba, Saitama Cancer Center, Dept. of Epidemiology, *818 Komuro, Ina-Machi, Kitaadachi-Gun, Saitama-Ken 362, Japan*

A high level of population flow would theoretically make a local mortality pattern unclear and it might be meaningful to group persons according to residential histories. In Saitama Prefecture, there is a high level of immigration from the whole of Japan. The standardized mortality rates for cancer have been calculated for several local populations (cities or towns) in Saitama Prefecture, using the death certificates for 1973-1977. After adjustment for residential history, it was shown that the relative risk of liver cancer among persons in some local populations was remarkably high. Death rates for liver cancer will now be studied in greater detail and it is intended to collect death certificates for a longer period of time. Ultimately an attempt will be made to identify causal factors.

CANCER INCIDENCE IN THE FRENCH DEPARTMENT OF BAS-RHIN

P. Schaffer, Universite Louis Pasteur - Universite de Strasbourg, Faculte de Medecine, Inst d'Hygiene et Medecine Preventive, *4 Rue Pascal, 67085 Strasbourg, France*

Cancer of all anatomical sites has been registered in the French department of Bas-Rhin since 1975. The registration area covers the resident population of Bas-Rhin: 883,095 inhabitants. The aims of the Registry are to establish incidence statistics for the identification of high-risk groups and for etiological research.

MALIGNANT NON-HODGKIN LYMPHOMAS IN UGANDA

R. Schmauz, Christian Albrechts Universitat, Medizinischen Hochschule, Inst fuer Pathologie, *Ratzeburger Allee 160, 2400 Lubeck, Federal Republic of Germany*

An attempt is made to describe the morphology and geographical distribution of these tumors using recent refined histological classifications. More than 500 cases coded under lymphosarcoma or reticulum cell sarcoma (ICD 200) are available for review from the Kampala Cancer Registry. It is hoped that some variation will be found within Uganda and in comparison to Europe which could provide clues to the nature of these diseases.

MORTALITY STUDY OF GLASS FIBER WORKERS

H.S. Shannon, McMaster University, Occupational Health Program, *1200 Main St. W., Hamilton, Ontario, Canada* L8S 4L8

A historical follow-up study is being conducted of 3,000-4,000 individuals who have worked in the manufacture of glass fiber since 1948. Mortality will be determined and certified causes of death found. Death rates will be compared internally (with rates in the provincial and national populations) and SMRs will be calculated. Of particular interest will be any deaths due to mesothelioma or lung cancer.

ANALYSIS OF THE CANADIAN CANCER INCIDENCE REPORTING SYSTEM AND ITS DATA, 1969-76

G.J. Sherman, University of Toronto, Faculty of Medicine, *92 College St., Toronto, Ontario, Canada* M5S 1A8

Although cancer incidence data collection has increased greatly in the last 15 years, relatively little use has been made of the data for epidemiological purposes. More fundamentally, traditional indices of incidence registration completeness seem inadequate. This study has two main objectives: (1) to survey cancer registration techniques used in Canadian provinces and to relate these findings to the results of mathematical modelling procedure which improves on the usual cases: deaths in period index of reporting, and (2) to examine existing Canadian incidence data with correlation, regression and multivariable stratification techniques which will result in testable etiological models when interpreted in the light of (1).

SPUTUM CYTOLOGY RELATED TO A FOUNDRY EXPOSURE

A. Simard, Institut du Cancer de Montreal, Centre Hospitalier Notre Dame, *1560 Sherbrooke St. E., Montreal, Quebec, Canada* H2L 4M1

Some studies have shown an increased risk of lung cancer among foundry workers. Sputum cytology among uranium miners has shown cellular changes ranging from mild, moderate and marked atypia to cancer in-situ and invasive cancer. Sputum cytology will be undertaken in 700 foundry workers, using the technique of Saccomanno. Results will be related to duration of exposure in the foundry. Information on age, date of entry into the industry, work history, and smoking history will be obtained and person-years at risk evaluated. Comparisons will be made with other exposed groups, namely uranium miners, asbestos workers and smokers.

SPUTUM CYTOLOGY AND ASBESTOS EXPOSURE

A. Simard, Institut du Cancer de Montreal, Centre Hospitalier Notre Dame, *1560 Sherbrooke St. E., Montreal, Quebec, Canada* H2L 4M1 (01913)

An increased risk of lung cancer among asbestos workers has long been known. Sputum cytology in uranium workers led Saccomanno to evaluate mild, moderate, and marked atypia as well as cancer in-situ and invasive cancer. Sputum cytology will be related to asbestos exposure in 800 workers. Short (10 years), medium (10-20 years), and long (20 years) exposure will be defined as well as degree of exposure (2 fibres/cc, 2-10). A special group of workers with 35 years of exposure (20-50 fibres/cc) will also be studied. Work histories and other data, namely age, smoking patterns, man-years at risk and years since first exposure, will be put on computer files and related to the severity of atypia.

MORTALITY SURVEY OF CEGB RADIATION WORKERS AND EX-WORKERS

G.A. Harte, Central Electricity Generating Board, Health Physics Research Section, *Berkeley GL13 9PB, Gloucester., United Kingdom*

The objective of the study is to determine whether exposure to low levels of ionizing radiation affects cause of death - in particular whether cancer mortality is higher in people occupationally exposed. Data is to be collected initially on 5,000-6,000 ex-workers, but eventually the study will be extended to current radiation workers (marking about 12,000 in all) and the survey will then run continuously. The exposed population will be compared with the general population, the working population, and eventually it is hoped, control groups within the electricity supply industry.

CYTOLOGICAL SCREENING FOR LUNG CANCER IN WORKERS EXPOSED TO HEXAVALENT CHROMIUM IN A CHEMICAL PLANT

R.M. Herivan, Ministry of Chemical Industry, Labour Protection & Hygiene Centre, Lab of Cytology, *59 Pop de Basesti, 73244 Bucharest 3, Romania*

The object of the study is to monitor 50 workers exposed to hexavalent chromium in a department in which chromium catalyst is manufactured, using cytological screening of sputum for the early detection of lung cancer as well as of epithelial disorders which may precede the development of a tumor. Annual cytological screening of sputum collected for three consecutive mornings and kept in Eskenasy fixative solution is carried out. Paraffin was added and the sputum dyed with HE and Masson. Results are correlated with age, sex, smoking habits, length of exposure, pulmonary antecedents, and exposure levels.

COHORT STUDY OF ASBESTOS-RELATED ILLNESSES IN WORKERS PREVIOUSLY EXPOSED TO ASBESTOS IN A SALTPETER PLANT

B. Hilt, Telemark Sentralsjukehus, Dept. of Occupational Medicine, *Olavsgt. 26, 3900 Porsgrunn, Norway*

The study is designed as a retrospective and prospective mortality and morbidity cohort study on the effects of occupational exposure to asbestos in a saltpeter plant located in southern Norway. The cohort consists of all men directly and indirectly exposed to asbestos dust in two divisions of the plant, and who started work there between 1929 and 1970. This includes about 320 persons. Based on assumed different levels of exposure, the cohort is divided up into subgroups. Most of the still living 160 men have been subjected to a medical examination which also includes a chest x-ray and simple spirometry. A detailed work history is taken from every man and respiratory symptoms are registered on a questionnaire (Medical Research Council, 1976). The cohort will be followed up by yearly examinations for a least five years. Occupational data on the dead members of the cohort are obtained from the plant's personnel department. Health data will be obtained from the plant's medical department, from the local hospital and from the Norwegian Cancer Registry. Data on smoking habits are collected from different sources and will be taken into consideration in the statistical calculations. The main aim of the study is to contribute to the design and justification of screening programs for former asbestos workers. It is also hoped to further knowledge on dose-response and dose-effect relationships.

3.1885,

CANCER INCIDENCE AND MORTALITY AMONG RAILROAD WORKERS

G.R. Howe, University of Toronto, *Medical Sciences Bldg., Toronto, Ontario, Canada* M5S 1A8

In a recent case-control study (Tobacco Use, Occupation, Coffee, Various Nutrients, and Bladder Cancer, G.R. Howe et al. JNCI, in press) an association was observed between any occupation related to railroads and increased risk of bladder cancer. The present study is a cohort study using pension records from a large Canadian railroad company. Records from 1965 onwards are being linked using computerized techniques, to the Canadian mortality data base, and records for those from 1969 on are being linked to the Canadian cancer incidence reporting system. Thus mortality between 1965 and 1976, and cancer incidence between 1969 and 1976 can be related to various occupations within the railroad industry.

HEPATOCELLULAR CARCINOMA IN URBAN BLACKS - ETIOLOGICAL FACTORS AND RELATIONSHIP TO CERTAIN ONCO-FETAL ANTIGENS

C. Isaacson, South African Inst. for Medical Research, Dept. of Histopathology, *Hospital St., P.O. Box 1038, Johannesburg 2000, Transvaal, South Africa*

Hepatocellular carcinoma has a high incidence in Southern Africa. Numerous series have shown a strong relationship with HBV. A preliminary study was performed using orcein staining for HBsAg on autopsy material obtained from patients dying of hepatocellular carcinoma at Baragwanath Hospital. A low positivity was noted. This was extended in a study using immunoperoxidase and aldehyde-fuchsin staining techniques on similar material. Seventeen percent of the Baragwanath series showed HBsAg positively in non-neoplastic liver as opposed to 72% in a control group of Shangaan miners from Mozambique. significant number of cases showed iron overload and micro-nodular cirrhosis in the Baragwanath series. A prospective study is now commencing using serological and immunochemical techniques to invostigate the relationship between various tumor-related antigens, including HBsAg, alpha-fetoprotein, carcinoembryonic antigens and ferritin, and hepatocellular carcinoma in the urban black population.

ETIOLOGY OF HODGKIN'S DISEASE

H. Isager, General Hospital, Dept. of Infectious Diseases, *Tagensvej 20, 2200 Copenhagen N, Denmark*

The risk of Hodgkin's disease (HD) is known to be inversely related to sibship size. In an on-going study of case-control-within-a-cohort design, using as a reference population the birth cohort 1930-1950 from the register of school health records from the Copenhagen council, an inverse relationship between risk of HD and birth order position has been found. Birth weight and height and weight at 8-14 years were also higher in patients than in controls. The study includes 63 HD patients and 183 controls. Information about sibship size, mother's age at birth, and the difference in age from the nearest older sibling is now being collected and will be analyzed in combination with information about birth weight, height and weight measured at school age, and social background. The aim is to evaluate the relative importance of these factors, using a method based on a linear logistic model.

ASSOCIATION OF STEROID CONTRACEPTIVE USE AND CERVICAL CARCINOGENESIS

W. Isarangkul Na Ayuthya, Mahidol University, School of Medicine, Dept. of Pathology, *Bangkok, Thailand 7*

The aim is to determine if there is a true association between steroid contraceptive use and cervical carcinogenesis and to identify high-risk groups for whom the use of steroid contraceptives might lead to a significantly increased risk of cervical dysplasia and cancer. A case-control study on women with cervical intraepithelial neoplasia and/or invasive carcinoma in which patients undergoing hysterectomy without histological evidence of the studied diseases serve as controls is being carried out. The two groups will be matched for age, age at first marriage, age at first pregnancy and socio-economic status. The subjects are interviewed for information on matching factors and contraception using a specially designed protocol. Histological sections of both case and control subjects are reviewed and the diagnoses confirmed. Additional serial sections of the cervix are obtained whenever necessary. Three hundred control and 300 case subjects will be investigated. Association will be evaluated by means of relative risks, statistical significance, and confidence interval.

EPIDEMIOLOGICAL STUDY OF DIET AND STOMACH CANCER

M. Jain, University of Toronto, *Medical Sciences Bldg., Toronto, Ontario, Canada* M5S 1A8

The object is to investigate the hypothesis that dietary factors are related to stomach cancer and specifically that nitrosamines are formed in the stomach from the interaction of amines and nitrites of dietary origin. Factors known to increase or reduce the formation of nitrosamines will be investigated. This case-control study is being conducted in three different provinces of Canada admitting approximately 400 newly diagnosed cases of stomach cancer and an equal number of population controls. Information is being collected by means of personal interviews using a personal and medical history questionnaire. The dietary information collected will include the frequency and amount of consumption of various foods and also any changes from present intake. In addition, the patterns or combinations of foods consumed for different meals will be assessed to assess the role of supposedly protective foods like vegetables and fruits.

BACKGROUND VARIABLES IN LUNG CANCER

S.K. Jindal, Postgraduate Inst. of Medical Education & Research, Dept. of Chest Diseases, *Chandigarh 160012, Punjab, India*

Lung cancer is being increasingly diagnosed all over the world. The reported incidence differs in different countries and populations, and environmental factors obviously play an important role. The present study aims to assess the risk from different smoking habits prevalent in India such as cigarette, bidi and hookka smoking, and to identify the role of rural/urban factors and occupation. Detailed information on smoking history, occupation and residence is obtained by interview of clinically and histologically confirmed cases of bronchogenic carcinoma seen over the past five years. 300 cases have been studied to date. preliminary report on 150 cases was published in 1979.

EFFECT OF SCREENING FOR BREAST CANCER IN ICELAND

G. Johannesson, Krabbameinsfelag Islands, Detection Center, *Sudurgata 22, P.O. Box 523, 121 Reykjavik, Iceland*

Since 1973 a clinical breast examination has been carried out on every woman being screened for cervix cancer. In selected cases a mammography and fine needle aspiration are also performed. About 10,000 women, or 25 percent of the female population of Iceland in the age group 25-70 years, are examined every year. From the cancer registry information is collected annually concerning all cases of breast cancer. The screening history, stage distribution, and survival rate of cases diagnosed by and without screening are compared.

EPIDEMIOLOGY OF URINARY TRACT CANCER IN GREATER BOMBAY

D.J. Jussawalla, Tata Memorial Hospital, Dept. of Surgery & Chemotherapy, *Dr. Ernest Borges Marg, Parel, Bombay 400012, Maharashtra, India*

For this study the data collected by Bombay Cancer Registry for the period 1964-75 have already been reviewed. A total of 954 cases of bladder and kidney cancers have been recorded. The incidence rates for bladder and kidney cancer are 2.8 and 1.3 for males and 0.9 and 0.8 for females, respectively. The incidence and mortality of these cancers by age, sex, religion and histology will be studied and the figures will be compared with those from other registries. A retrospective analysis of these cases will also be carried out in order to study the relationship of urinary tract cancers with smoking habits, alcohol addiction and dietary patterns.

CANCER INCIDENCE IN AURANGABAD CITY AGGLOMERATION

D.J. Jussawalla, Tata Memorial Hospital, Dept. of Surgery & Chemotherapy, *Dr. Ernest Borges Marg, Parel, Bombay 400012, Maharashtra, India*

Western Maharashtra, Marathwada and Vidarbha are the three natural divisions of Maharashtra. Aurangabad City, covering an area of 50.48 sq. km with a population of 165,253 (1971 Census), is the main city in Marathwada. The purpose of this study is to obtain reliable morbidity data on cancer from this precisely defined area. Apart from in Bombay and Poona no such stuies have been carried out in India. Data on cancer patients are collected on pre-designed proformas from 12 general hospitals, 51 dispensaries, 3 clinics and 3 family planning centers. Copies are made of all death certificates which mention cancer as a cause of death from the vital statistics division of the Aurangabad Municipal Corporation.

CANCER MORTALITY IN GREATER BOMBAY

D.J. Jussawalla, Tata Memorial Hospital, Dept. of Surgery & Chemotherapy, *Dr. Ernest Borges Marg, Parel, Bombay 400012, Maharashtra, India*

Until 1941 cancer was not included in the list of the 10 leading sites of death in Greater Bombay, but today it ranks ninth, and is responsible for 4.3% of all deaths in the city. Data on cancer mortality were collected from the Vital Statistics Division of the Bombay Municipal Corporation. A total of 21,958 cancer deaths were registered among residents of Greater Bombay during the period 1964-74. The aim of this study is to analyze these data by age, sex, and site and to compare these rates with the mortality experience of other countries. Age-specific cancer rates will be used for computing the data.

CASE-CONTROL STUDY OF BREAST CANCER IN NORTH EAST BRAZIL

A. Kalache, University of Oxford, Dept. of Social & Community Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom*

The North East of Brazil is a poor, underdeveloped area, but in contrast with other similar regions in the world, breast cancer is remarkably common; in Racife and Fortaleza (the two biggest cities in the area) the incidence among women aged 35-64 years is nearly 100/1000000/year, only slightly less than the rate for women of similar age in England. Clues to disease etiology may often be gleaned from the study of exceptional situations and it is hoped that a case-control study will lead to the isolation of some specific factor which may be responsible for the high incidence of breast cancer in Brazil. The study will take two years and will be conducted simultaneously in Recife and Fortaleza; for each case there will be two controls and the interviews will concentrate on currently known risk factors and also on specific aspects related to local diet and habits.

CANCER AND OCCUPATIONAL EXPOSURE TO INDUSTRIAL POLLUTANTS

H. Kjuus, Telemark Sentralsjukehus, Dept. of Occupational Medicine, *Olavsgt. 26, 3900 Porsgrunn, Norway*

Suggested estimates of the proportion of cancers attributable to occupational exposure varies widely. This case-referent study aims to assess to what degree cancer among patients in a county hospital is related to occupational exposure. A complete working history is obtained from all male patients admitted to surgical and medical wards with newly diagnosed cancer, and the total number of years of occupational exposure to a variety of industrial pollutants is recorded. The reference group consists of age-matched non-cancer patients from the same wards. There will be approximately 100-150 cancer patients in the case group.

CANCER INCIDENCE AMONG FERROCHROMIUM AND FERROSILICON WORKERS

S. Langard, Telemark Sentralsjukehus, Dept. of Occupational Medicine, *Olavsgt. 26, 3900 Porsgrunn, Norway*

The aim is to evaluate whether workers exposed to trivalent chromium have an increased risk of developing lung cancer or cancer at other sites by means of a historical study carried out on a population producing ferrosilicon and ferrochromium from 1928. The whole study population includes 976 members of whom 325 are characterized as belonging to a ferrochromium subpopulation. The internal reference population is comprised of workers who have not been exposed at the ferrochromium furnaces. The mortality and cancer incidence in the population is followed from 1935 through 1977. A complete working history of all members of the population is recorded, and an industrial hygiene survey performed. The mortality is compared to that for similar age-groups in the Norwegian population and incidence rates are compared with those for both the total Norwegian population, a local population and an internal population.

CANCER OF THE UPPER LIP

C.J. Lindqvist, Finnish Cancer Registry, *Liisankatu 21 B, 00170 Helsinki 17, Finland*

The epidemiology of lip cancer has been thoroughly studied during recent years in Finland (Am. J. Epidemiol., 109, 521-530, 1979). Cancer of the upper lip has, however, not been analyzed separately. Differences in male/female ratios of the incidence rates, time-trends, age-incidence curves, urban/rural ratios and geographical distribution in the different provinces of Finland suggest that the risk factors in upper and lower lip cancers may be different. The material consists of all cases of cancer of the upper lip diagnosed in 1953-1975 and reported to the Finnish Cancer Registry. The epidemiology of upper lip cancer will be studied, and compared and correlated with data on total lip cancer together with some other types of cancer with the aim of testing certain etiological hypotheses.

INTERACTION BETWEEN SMOKING AND ASBESTOS EXPOSURE IN LUNG CANCER AMONG CHRYSOTILE MINERS AND MILLERS

F.D. Liddell, McGill University, Dept. of Epidemiology & Health, *3775 University St., Montreal, Quebec, Canada* H3A 2B4 (01996)

In the 'Quebec Asbestos Mortality Cohort', consisting of 10,939 males and 440 females born 1891 through 1920 who worked for at least a month in the chrysotile mines and mills of Quebec, there had been 4,463 male deaths to the end of 1975. Of these, 244 were due to lung cancer, and, for a study under the direction of Professor J.C. McDonald, four controls had been selected from the cohort for each lung cancer death; the controls were born in the same year as the case, but had survived to a greater age. Work histories have been verified and annual exposures to chrysotile calculated in terms of fiber concentrations times proportion of year worked. Smoking history questionnaires had been completed for the great majority and are being recorded. New methods for comparing the fits of several models of observable interactions of the combination of asbestos and smoking in causing disease will be applied, leading to the possibilities of (a) inferences concerning biological models of carcinogenesis, and (b) the estimation of the probabilities that any individual's cancer was due to smoking or to asbestos exposure or to other factors.

A RETROSPECTIVE STUDY OF CANCER IN RELATION TO A SPECIFIC ENVIRONMENTAL FACTOR (WATER NITRATE)

P. Lumholtz Frederiksen, KAS Herlev, Dept. of Radiotherapy & Oncology, *Herlev Ringvej, 2730 Herlev, Denmark* (01379)

The incidence of testis cancer in Denmark has for years been known to exceed that of neighboring countries (6.0 new cases/year/100,000 males). In this study a small, geographically limited 'hot-spot', possibly of recent origin, with an incidence of 31.7 new cases/year/ 100,000 males during the last two years (01.06.76 - 01.06.78) has been detected. This particular region differs from the rest of the island of Sjaelland (the island where the capital Copenhagen is situated) in one specific respect: the content of nitrate in deep ground-water supplies. The possibility

of the formation of carcinogenic nitrosamines from nitrate, nitrite and secondary amines in humans is being examined. Data are now being collected to see if there is a significant rise in the incidence in other parts of the country.

EPIDEMIOLOGICAL STUDY OF YOUNG PATIENTS WITH UTERINE CANCER

K. Masubuchi, Cancer Inst. Hospital, Dept. of Gynaecology, *1-37-1 Kamiikebukuro, Toshima-ku, Tokyo 170, Tokyo, Japan*

In recent years, there have been many reports on cervical cancer in young women. The objective is to study cervical carcinoma and corpus carcinoma in young patients epidemiologically. Among 6,336 cases of cervical carcinoma and 467 cases of corpus carcinoma treated in the Department of Gynaecology, the Cancer Inst. Hospital in Tokyo from 1949 to 1977, 873 patients with cervical carcinoma and 17 patients with corpus carcinoma were under 39 years of age and these are being analysed. Non-cancer patients operated on at the same time and of the same age are selected as a control group.

LONG-TERM EFFECTS OF THE HEALTH STATE OF OCCUPATIONAL EXPOSURES TO CHEMICALS

R. Maties, Academia de Stiinte Medicale, Inst. of Hygiene & Public Health, Dept. of Occupational Medicine, *Strada Biserica Amzei 29, Bucharest, Romania*

Malignant tumors as well as cardiovascular and obstructive lung diseases may be caused by occupational exposure to various chemicals. The aims of the project are (1) to develop a suitable epidemiological methodology; (2) to analyze accurately the long-term effects of occupational exposure to chemicals, and (3) to determine the specific patterns of morbidity and mortality from malignant tumors in workers formerly exposed to chromium salts, asbestos and aromatic amines. The project includes a study of mortality from lung cancer, pleural mesothelioma and bladder cancer over the last 20 years in workers exposed to various chemicals, compared to the mortality recorded in the general population of the area, and a morbidity study based on the result of periodic medical examinations performed annually among workers at risk.

LUNG CANCER - SMOKING, RESIDENCE AND WORK PLACE EXPOSURES

C. Edling, University of Linkoping, University Hospital, Dept. of Occupational Medicine, *58185 Linkoping, Sweden*

Radon concentrations are expected to increase in dwellings due to decreased ventilation for energy saving. Estimates by the Swedish Energy Commission indicate that radon and radon daughters in dwellings could contribute considerably to lung cancer morbidity. Recently a case-control study from an extremely rural area indicated an increased risk of lung cancer among residents in stone houses (i.e. the higher concentrations of radon and daughters) in comparison to those who had lived in wooden houses (low concentrations) (Scand. J. Work Environ. Health, 5, 10-15, 1979). Another case-referent study has started to examine the hypothesis that indoor concentrations of radon and daughters are of etiological importance for lung cancer. Type of residence, work place exposures, smoking, etc. are examined in 120 newly diagnosed lung cancer cases and 480 matched controls selected from hospital registers. If earlier results are confirmed, efforts to save energy through decreasing ventilation mean a serious lung cancer threat to the populations in countries with a cold climate. However, if this hazard can be more definitely assessed, indoor air could be filtered to remove radon daughters.

OCCUPATION AND NASAL CANCER

U.K. Engzell, Huddinge Sjukhus, Dept. of Ear Nose & Throat, *S14186 Huddinge, Sweden*

An increased frequency of cancer of the nose and paranasal sinus among workers exposed to fine wood dust, leather and nickel has been reported from England and other countries. A joint project has been started to explore the risk of contracting nasal cancer in the Nordic countries and to single out occupations and exposures possibly associated with nasal cancer. In each country a project group is at work on a national basis, according to a joint program. Each new case of malignant epithelial tumor of the nose and sinuses reported to the individual national cancer registries is interviewed concerning previous occupational exposures of various kinds. There are an estimated 150 cases a year. The project is a case-referent study and the controls will be matched cases of colon cancer.

3.1923,

CASE-CONTROL STUDY OF SOFT TISSUE SARCOMAS AND EXPOSURE TO CHEMICAL AGENTS

M.H. Eriksson, Regionsjukhuset, Dept. of Oncology, *90185 Umea, Sweden*

In 1978 a matched case-control study performed in this insitution showed that exposure to phenoxyacetic acids or chlorophenois gave an approximately sixfold increase in the risk of soft tissue sarcomas. This investigation was carried out in the northernmost counties in Sweden, where forestry is common. All exposed cases except two had been in occupational contact with either chlorophenols or the phenoxyacetic acid 2,4,5-T (2,4,5-trichlorophenoxyacetic acid), which are both often associated with impurities such as chlorinated dibenzodioxins or dibenzofurans, among them the toxic 2,3,7,8-tetrachlorodibenzodioxin (TCDD). Thus it could not be decided whether the increased risk was due to the impurities or to the chemicals studied. To try to determine this, a new matched case-control study is being carried out in the agricultural area of the five southernmost counties in Sweden, since phenoxyacetic acids without the impurities mentioned above are extensively used in farming. The cases in this new study are 110 men, aged 25-75, with soft tissue sarcomas diagnosed between 1974 and 1978 in the region studied. For each case two controls are selected, matched by geographical district, sex and age.

MORTALITY RISK STUDY OF COPPER SMELTER WORKERS

L. Frappier Davignon, Armand Frappier Institut, Centre de Recherche en Epidemiologie et Medecine Preventive, *531 Blvd. des Prairies, Case Postale 100, Laval des Rapides, Quebec, Canada* H7N 4Z3

The study aims to determine if an excess risk of mortality from certain diseases, especially lung, renal or prostate cancer, exists among copper smelter workers. These workers are exposed to lead, arsenic, cadmium and sulphur dioxide. Five levels of exposure to these different contaminants have been determined: (1) no exposure; (2) exposure to concentrations always below the threshold limit values (TLV) accepted by the National Inst. of Occupational Safety and Health (US); (3) average exposure below TLV but with possible incursion over; (4) average exposure always over TLV; (5) exposure known but never measured. Employees who have worked at least one year for the company between 1 January 1952 and 31 December 1957 are followed up to 31 December 1977. In all 2,246 workers will be studied. The risk of mortality related to different cancers will be evaluated by comparing the number of cancers observed in a cohort to the number expected in a population of the same age and sex, for each year, in the Province of Quebec.

LUNG CANCER - HISTOLOGY AND OCCUPATIONAL EXPOSURE

M. Geddes, Center for the Prevention of Social Diseases, Unit for Epidemiological Research in Environmental Toxicolog, *171 Viale Alessandro Volta, 50131 Florence, Italy*

An association has been observed between some occupations and specific histological types of lung cancer. The present study aims to verify if there is a different distribution of workers and others between various histological types of lung cancer; and to determine if there is a different distribution of occupational groups specifically exposed to carcinogens for lung in humans (IARC working group report, 1978) in lung cancer patients with different histological types and in controls. Approximately 500 lung cancer patients (males and females), with established histological diagnosis according to a simplified WHO classification, and an equal number of controls selected from the same hospital, without respiratory diseases, hospitalized in the same year, and matched for sex, age, residence and smoking habits are interviewed about occupational history, which is classified according to the International Labor Organization classification.

CANCER RISK IN NON-FERROUS METALLURGY AND CHROMIUM INDUSTRIES

S.I. Gabor, Academia de Stiinte Medicale, Inst. of Hygiene & Public Health, Dept. of Occupational Health, *Pasteur 6, 3400 Cluj Napoca, Romania*

Exposure of workers to lead, cadmium, copper, arsenic, chromium and sulphur dioxide from non-ferrous metallurgy and chromate industries, as well as that of the population living in the surrounding polluted areas, represents a risk of high cancer incidence. This investigation aims at assessing the mortality patterns of retired workers employed in non-ferrous metallurgy (lead and copper smelting) and chromium compound production plants compared to the mortality rate of the general population. Environmental measurements will be carried out in parallel with biotoxicological tests of exposure and sputum cytology screening examinations. As estimated, 1,500 workers will be surveyed.

STUDY OF THE EPIDEMIOLOGY, HISTOPATHOLOGY, AND CLINICAL PATTERN OF MELANOMA IN NORTHERN IRELAND

L. Gordon, Queens University of Belfast, Dept. of Oncology, *Belfast, Northern Ireland, United Kingdom*

The first retrospective study of the pattern of melanoma in Northern Ireland (1974-1978) is being undertaken, encompassing about 300 cases. Histopathology is classified according to both the Clark and Breslow criteria. Additional features such as tumor profile, cell type, ulceration, mitoses, and lymphocytic infiltrate pattern are being noted. A clinical picture of each patient is also recorded, including selected aspects of personal history. Advantages claimed for this study are (1) geographical completeness, (2) the investigation of clinical, histological, and epidemiological factors as they inter-relate to one another. A comparative study to illuminate the interaction between genetic factors and the environment will follow. The results of the study of the native Irish population could profitably be compared with Irish immigrant populations in Australia, the USA, and Canada.

BRONCHUS CARCINOMA IN URANIUM MINERS (SCHNEEBERGER LUNGENKREBS)

E.F. Hain, Allgemeines Krankenhaus, Dept. of Pneumology, *Bissendorfer Pferdeweg 52, 2000 Hamburg 90, Federal Republic of Germany*

Bronchus carcinoma is being studied in 47 cases found in uranium miners in the Federal Republic of Germany after the Second World War. 45 of these persons were exposed to uranium in Saxony/Bohemia outside the Federal Republic of Germany. All data, especially the radiation measurements, of these miners are kept secret, so that it is impossible to measure the real radiation exposure. This is estimated by the time of exposure to uranium. No control group is used because of this lack of information. Besides time of exposure the following data are collected: age at death, latency period, place and type of uranium mining, therapy, time of survival after discovery of the carcinoma, site and histology of the carcinoma, metastases, clinical data, pneumoconiosis, and smoking history.

3.1933,

MALIGNANT LYMPHOMAS AND EXPOSURE TO CHEMICALS, ESPECIALLY TO PHENOXYACETIC ACIDS, CHLOROPHENOLS OR ORGANIC SOLVENTS

O.L. Hardell, Regionsjukhuset, Dept. of Oncology, *90185 Umea, Sweden*

In 1977 a number of patients with soft tissue sarcomas and previous exposure to phenoxyacetic acids were reported in this department. This included an analysis of exposure to chlorophenols. The results showed that exposure to phenoxyacetic acids or chlorophenols gave an approximately six-fold increase in the risk for this type of tumor. In May, 1978, a patient with a tumor in the soft tissue of his left femur was admitted to this department. The clinical picture was similar to that of a soft-tissue sarcoma. Histological examination showed, however, a malignant lymphoma of histiocytic type. The patient reported a massive exposure to phenoxyacetic acids. All male patients with this type of tumor who were admitted to the department during January to September, 1978, were then asked about their past and present occupation and about possible exposure to phenoxy acids or chlorophenols. In this pilot study, 14 of 17 patients reported a current occupation which was consistent with the possibility of exposure to the chemicals under study - namely, farming or forestry (7), saw mill work (1), painting (3) and building (3). Eleven men reported exposure to phenoxyacetic acids or chlorophenols. An epidemiological study is now being performed. The cases are 173 men with malignant lymphomas, aged 25-85 years, admitted to this department in 1974-1978. For each case two controls are selected, matched by geographical region, sex and age. The chemicals under consideration are phenoxyacetic acids, chlorophenols and organic solvents.

EPIDEMIOLOGY, PATHOLOGY, CLINICAL MANAGEMENT AND OUTCOME OF MALIGNANT MELANOMA IN WESTERN AUSTRALIA

B.K. Armstrong, University of Western Australia, *Nedlands, W. Australia 6009, Australia*

All patients (about 500 expected) having pre-invasive or invasive malignant melanoma of the skin diagnosed in Western Australia in 1980 and 1981 will be included in a case-control study, and detailed review of histopathology and clinical management undertaken. The case-control study will include demographic features, details of sun-exposure (particularly intermittent versus continuous), objective measures of solar skin damage, diet and other relevant habits. Controls will be matched by age and sex using the electrical roll as a sampling frame. All relevant prognostic features will be recorded in the histopathological review including Clark's levels and tumor thickness. Melanoma patients will be followed for at least ten years to document prognosis in relation to histopathology and clinical management.

EPIDEMIOLOGICAL ANALYSIS OF HOSPITAL DIAGNOSIS DATA

T. Abelin, Universitat Bern, Dept. of Social & Preventive Medicine, *Waldheimstrasse 18, 3012 Bern, Switzerland*

For most cancer sites, patients are admitted to a hospital at some point of the disease process. Analysis of country-wide hospital diagnosis statistics thus allows for insights into time trends of cancer incidence by regions and socio-demographic characteristics. In the present study, hospital diagnosis data (available for about one-third of all acute hospital departments in Switzerland) will be extrapolated in stratified procedure to the country as a whole and to socio-culturally different regions. Cancer incidence will be computed for all major sites, and analysis will focus on correlations with personal and regional characteristics. Emphasis will be on cancer sites known to be associated with tobacco and/or alcohol consumption. Data will be drawn from the VESKA-hospital diagnosis statistics system, existing since 1969, that today includes 309 hospital departments with approximately 300,000 yearly admissions.

SURVEY OF THE PREVALENCE OF FERRUGINOUS BODY (ZEOLITE) IN SPUTUM OF THE INHABITANTS OF KARAIN

Y.I. Baris, Hacettepe Universitesi, Faculty of Medicine, Dept. of Chest Diseases, *Ankara, Turkey*

Recent epidemiological work carried out in the village of Karain revealed that malignant mesothelioma and chronic fibrosing pleurisy are endemic. Mineralogical data show that these disorders are probably due to the presence of a fibrous silicate (zeolite) other than asbestos which is found in the tuff rocks in Karain, in the airborne samples and even in the lung tissues of the patients. A survey is planned in order to demonstrate ferruginous bodies (zeolite) in the sputum of the inhabitants of Karain using the neighboring village of Karlik as a control. The level of exposure will be assessed and correlated with cancer rates.

CLINICAL AND RADIOLOGICAL STUDY OF SEPIOLITE WORKERS

Y.I. Baris, Hacettepe Universitesi, Faculty of Medicine, Dept. of Chest Diseases, *Ankara, Turkey*

It has already been shown that mineral fibers are potentially active biologically. Because of this it was decided to carry out a clinical and radiological study in workers who take part in the production and manufacturing of sepiolite. A clinical and radiological study is being done on 63 sepiolite processing workers in Eskisehir and radiological findings are collected on mass survey (70 mm films) in four villages where mining and processing of sepiolite have taken place for more than a hundred years.

A TIME-SPACE CLUSTERING ANALYSIS OF CHILDHOOD MALIGNANCY IN NORTH WEST ENGLAND
J.M. Birch, University Hospital of South Manchester, Dept. of Epidemiology & Social Research, *W. Didsbury, Manchester M20 8LR, England, United Kingdom*
Previous studies of this type have been carried out on leukemias and some lymphomas and have produced negative results or evidence of weak clustering. The Manchester Children's Tumor Registry is population-based with almost complete ascertainment and a high degree of diagnostic accuracy. It therefore provides a unique body of data for this type of analysis. The address at the time of each child's birth is known and it is felt that in the case of childhood cancer this may be more appropriate reference than the address at time of onset of the disease. Two Ordnance Survey grid references, accurate to within 0.1 Km, have been allocated to each case included in the Manchester Children's Tumor Registry between 1 January 1954 and 31 December 1973 corresponding to the child's place of residence at its time of birth and at the time of onset of its disease. These data are being analyzed, using the methods described by Pike and Smith, 1968, and Smith et al., 1976, to detect any space-time interaction. The data will be analyzed as a whole, by disease group and by age group.

A STUDY OF CHILDHOOD LEUKEMIA IN NORTH WEST ENGLAND 1954-1977
J.M. Birch, University Hospital of South Manchester, Dept. of Epidemiology & Social Research, *W. Didsbury, Manchester M20 8LR, England, United Kingdom*
The annual incidence of leukemias of various cell types recorded by the Manchester Children's Tumor Registry during the period 1954-1977 has been analysed and the incidence of acute lymphoid leukemia has shown a significant increase. The data are currently being analysed to determine whether this increase is concentrated in any particular group. Factors being studied include age, sex, white cell count at presentation, social class and socio-economic group. Geographical studies are also being carried out to determine incidence trends in different parts of North West England and any association with features specific to a given area. A prospective case-control study of possible etiological factors (with emphasis on genetic and other pre-natal factors) will begin early in 1980. Controls will be selected from the population and matched for age, sex and race.

VIENNESE GYNECOLOGICAL TUMOR REGISTRY
G. Breitenecker, Universitat Wien, Medizinischen Fakultat, *Spitalgasse 23, 1010 Vienna, Austria*
In Austria, gynecological tumors are the cause of 20% of all deaths of females from cancer. At present some one million vaginal smears are examined in Austria annually. However, the number of women screened is not known as there is no registration of individuals and no record is kept of frequency of repeated examinations. Only inaccurate figures are available on the prevalence and incidence rates of gynecological cancers and, although mortality statistics provide the most reliable existing data, these cannot be used for epidemiological investigations as the localization of uterine cancer is not reported in nearly two-thirds of cases, so that the annual death rate for women with cervical cancer versus endometrial cancer is not clear. The aim is to organize a gynecological tumor registry in the Viennese area, which could eventually form part of a state-wide cancer registry. In addition to improving mortality and morbidity data and determining incidence and prevalence rates and effectiveness of treatment, there will be patient-based registration of cytological reports to determine prevalence and incidence rates of pre and early stages of cervical cancer and to evaluate screening programs. Cooperation with federal and community institutions, the Austrian League Against Cancer and gynecological and pathological institutes and practitioners will be extended.

EPIDEMIOLOGY OF DYSPLASIA AND CARCINOMA OF THE UTERINE CERVIX
J. Roy Chowdhury, Chittaranjan National Cancer Research Centre, Dept. of Epidemiology/Pathology, *37 S.P. Mukherjee Rd., Calcutta, 700026, West Bengal, India*
Carcinoma of the uterine cervix is the most common form of cancer among Indian women and more prevalent in low socioeconomic groups. It is accepted that a certain percentage of different grades of cervical dysplasia progress to squamous cell carcinoma. The aim of the present study is to establish the prevalence rate of dysplasia and cancer of the uterine cervix in the urban and rural population in West Bengal and correlate the natural histories of these lesions with age, parity, age at first birth, beginning of sexual relations, marital status, number of births and other known etiological and epidemiological factors. Married women in the age-group ranging from 20-70 years attending the Cancer Detection Centers are questioned thoroughly and forms containing 20 groups of questions are filled out by experts. The following investigations are made: general physical examination, systemic examination, gynecological examination, cytological and biopsy specimen examinations (biopsies are taken from the patients with cancer of the cervix and dysplasia whenever possible). Cases of dysplasia are followed up periodically for a minimum period of 5 years.

EPIDEMIOLOGY OF ORAL CANCER
J. Roy Chowdhury, Chittaranjan National Cancer Research Centre, Dept. of Epidemiology/Pathology, *37 S.P. Mukherjee Rd., Calcutta, 700026, West Bengal, India*
Oral cancer, the commonest form of cancer in Indian men, is often preceded by some white precancerous lesions. The objectives of the present study are to establish the frequency of both oral cancer and precancerous lesions in urban and rural populations in West Bengal and the frequency of malignant transformation of white precancerous lesions and to examine the distribution by age, sex, localization, tobacco chewing and smoking habits. Other possible etiological factors, such as nutritional and dietary factors, oral hygiene, use of dental prosthesis and alcohol consumption, are also being investigated.

INDUSTRIAL POLLUTION AND CANCER
N.W. Choi, Manitoba Cancer Treatment & Research Foundation, Dept. of Epidemiology & Biostatistics, *700 Bannatyne Ave., Winnipeg, Manitoba, Canada* R3E OV9
Objectives of the study are: (1) to investigate if risks of certain cancers were increased among the employees of a mining and smelting company according to length and place of job in the company and (2) to investigate if risks of certain cancers were also increased for the neighboring community. If so, the increased risk in relation to employment status and/or the relationship of the cases to employees will be further determined. In achieving both objectives, certain important variables such as smoking and dietary habits will be accounted for. Most of the feasibility work has been completed in terms of identification of the cohort group (approximately 30,000), population at risk, linkage of study subjects to a number of different sources of health and vital statistics including our cancer registry and follow-up of the cohort group, etc. As the feasibility of such a study has become apparent, a definitive study will now be conducted.

3.1953,
CANCER AMONG ICELANDERS IN CANADA AND ICELAND
N.W. Choi, Manitoba Cancer Treatment & Research Foundation, Dept. of Epidemiology & Biostatistics, *700 Bannatyne Ave., Winnipeg, Manitoba, Canada* R3E OV9
In preparation for a series of studies on health and chronic diseases in Icelanders in Canada and Iceland initiated by consortia of Canadian and Icelanic scientists, a feasibility study of identification of cohort groups, data linkage and follow-up of study subjects has been conducted and is being completed. An initial study on cancer incidence among the Canadian Icelanders in relation to generation, relatives and geography has been planned. The objectives of the study are: (1) to study incidence of and mortality from cancer among Icelanders in Manitoba and Iceland; (2) to compare incidence of and mortality from cancer among different generations of Icelanders in

Manitoba with those among non-Icelanders in Manitoba and Icelanders in Iceland; (3) to compare incidence of and mortality from cancer between family members of Icelanders in Manitoba and Iceland; (4) to elucidate environmental correlates of differing incidence and mortality among Icelanders in Iceland and Manitoba.

NATIONAL AND INTERNATIONAL TRENDS IN MORTALITY FROM ALCOHOL-RELATED DISEASE

C.E. Chilvers, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom*

Alcohol consumption data are being collated from different sources for the United Kingdom and other countries. These will be related to cohort mortality trends for cancers of certain sites for which an association with alcohol consumption has been hypothesized, for example cancers of esophagus, larynx and colon and also for other chronic diseases. Correlations between mortality levels and alcohol consumption levels will also be investigated. The objective is to ascertain whether or not trends in these diseases are related to trends in alcohol consumption in the different countries. This should give some idea of which alcoholic beverages are particularly hazardous or whether there are other factors of more importance that should be investigated. This is particularly pertinent in countries such as the United Kingdom, where alcohol consumption is increasing and an increase in alcohol-related disease may be expected.

COMPARATIVE STUDY OF MORBIDITY AND RISK FACTORS OF FEMALE GENITAL CANCER IN THE GEORGIAN SSR, GERMAN DEMOCRATIC REPUBLIC AND POLAND

L. Charkviani, Ministry of Health of the Georgian SSR, Dept. of Gynaecology, *Lake Lisi, Tbilisi 380077, Georgia, Union of Soviet Soc. Republics*

Comparative studies of morbidity rates for cancer of the main sites of the female genital tract will be carried out in the Georgian SSR, German Democratic Republic and Poland for the period of 1971-1980. Morbidity rates will be analyzed by age and histological type. Analytical investigations will be carried out to identify risk factors. Each country will provide a certain number of questionnaires filled in for cases of gynecological cancer and for healthy controls. Comparative analysis of the morbidity rates and of the questionnaires from different countries will enable detection of risk factors.

OCCURRENCE OF CANCER IN THE SWEDISH TWIN REGISTRY

R. Cederloef, Karolinska Institutet, Dept. of Environmental Hygiene, *Solnavagen 1, Box 60400, S10401 Stockholm 60, Sweden*

In 1961 the Twin Registry covered about 10,000 pairs of the same sex born 1886-1925. The registry was expanded in 1973 to include about 13,000 pairs born 1926-1958. Cancer morbidity data have been obtained from the Swedish Cancer Registry and mortality data are continuously recorded for the twins. The first part of the project will be an evaluation of concordance rates among monozygons and dizygons twins with respect to a diagnosis of cervix and breast cancer. In addition, these diagnoses will be related to questionnaire data covering socio-economic factors, use of oral contraceptives, and smoking habits. Information on cancer of all sites is available and other specific diagnoses will be evaluated subsequently.

COHORT STUDY OF ASBESTOS-RELATED DISEASES AND MORTALITY IN ASBESTOS-CEMENT WORKERS

T. Burilkov, Medical Academy, Hygiene & Occupational Diseases Inst., Unit of Epidemiology, *15 Dimiter Nestorov St., 1431 Sofia, Bulgaria*

This cohort study aims to determine the asbestos-related diseases and the mortality pattern in a cohort of workers, exposed to chyrsotile asbestos in an asbestos-cement factory in Dimitrovgrad, Bulgaria. The asbestos exposure of 1,647 workers employed prior to 1960, the health status of persons alive and the causes of death for the period between 1960-1980 will be examined. Morbidity and mortality data will be compared with those expected for the population of the whole country and the town of Dimitrovgrad in an attempt to detect significant asbestos-induced health effects, their relation to occupational risk and the latent period between onset of exposure and clinical manifestation.

EPIDEMIOLOGICAL STUDY OF CEREBRAL TUMORS IN ADULTS

J.D. Burch, National Cancer Inst. of Canada, Epidemiology Unit, Dept. of Preventive Medicine & Biostatistics, *12 Queens Pk. Cres. W., c/o University of Toronto, Toronto, Ontario, Canada* M5S 1A8

Little is known of the etiology of cerebral tumors in humans, although associations have been suggested as a result of incidence, mortality, and animal studies. These include urban/rural differences, occupation with specific reference to farming, the rubber industry, and exposure to vinyl chloride, familial associations, ionizing radiation, brain trauma, and specific chemical carcinogens. The current study will reinvestigate these associations and explore other possible relevant factors. The study will test the hypotheses that cerebral tumors are associated with specific occupations (farming, rubber industry, plastics industry), family history of brain tumor, and exposure to nitrosamines, especially through drinking water and preservative-containing meats and meat products. A number of questions will also be asked of respondents relating to additional environmental factors (e.g., smoking, alcohol consumption, etc.). Data on past events and exposures will be obtained from cases and hospital controls through personal interviews in the respondents' homes using proxy respondents for dead or incapacitated cases and appropriate proxy controls. Case and control acquisition is restricted to the metropolitan Toronto and fringe areas and will include incident cases with defined histology for the four-year period 1 January 1977 to 31 December 1980.

3.1962,

EPIDEMIOLOGY OF CERVICAL DYSPLASIA

E.A. Clarke, Ontario Cancer Treatment & Research Foundation, Division of Epidemiology & Statistics, *7 Overlea Blvd., Toronto, Ontario, Canada* M4H 1A8

The proposed investigation is a case-control study designed to examine the relationship between cigarette smoking and dysplasia of the uterine cervix. Evidence has accumulated linking cigarette smoking and different sites of squamous cell carcinoma, recently including that of carcinoma of the uterine cervix. It is, therefore, possible that exposure to cigarettes may also increase the risk of cervical dysplasia which is a precursor of invasive carcinoma of the cervix. The cases will be 250 consecutive women between the ages of 20 and 59, seen at the Dysplasia Clinic of the Toronto General Hospital. Two controls will be used, the first being a neighborhood control selected for living as close as possible to the case and the second selected from the practice of the physician who referred the case to the Toronto General Hospital for treatment. Each case and control will be interviewed to obtain information on date of birth, education, income, marital status, race, gynecological and obstetrical history, contraceptive practices, sexual history and smoking habits. The analysis will explore differences between cases and controls in their smoking habits after taking appropriate account of such disturbing variables as socioeconomic status, etc.

CANCER MORTALITY AND WATER FLUORIDE

P.J. Cook, University of Oxford, Dept. of Social & Community Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom*

The age-standardized death rates for 'all malignant neoplasms' are being compared for the population of Birmingham (fluoridated in 1964) and the six other towns in England with a population over 400,000 (not fluoridated). Rates are being calculated for the periods 1959-63; 1969-73; and 1974-77. Allowance is being made for boundary changes which, if ignored, would invalidate comparison of the time trends. The situation in Birmingham is being considered in the context of studies comparing fluoridated and non-fluoridated populations in other countries because of the impossibility of drawing any etiological conclusions from a study of one 'affected' population. More detailed time comparisons by individual site and type of cancer are planned when unpublished data have been prepared by the Office of Population Censuses and Surveys. The latter will also permit geographical comparisons between the cancer mortality rates in all areas of England and Wales fluoridated before 1969 and eight neighboring control areas.

INTERDISCIPLINARY STUDIES ON NASOPHARYNGAEL CARCINOMA AND ASSOCIATED HUMAN TUMORS

G. De The, Centre National de la Recherche Scientifique, International Prog for Epidem & Exper Studies on Human Tumor, *Lyon, France*

The objective of the study is to determine the importance of Epstein-Barr virus immuno-virological tests for clinical management of nasopharyngeal carcinoma. The specific aims are to evaluate IgA antibodies to EBV in serum and saliva of NPC patients as a marker for prognosis; to evaluate EBV serology and EBV markers in tumor cells as complement to pathology to characterize malignancies arising in the nasopharynx, and to evaluate EBV serology as a tool for diagnosis in metastatic cervical lymph nodes with occult primary, and as a method of early detection in areas having high incidence for NPC. The project will involve the following closely linked sub-projects: (1) a prospective study involving all new NPC patients in Paris, Milan, Tunis and most of the patients in Hong Kong aimed at assessing the value of EBV immunovirology in the management of NPC, using clinical, pathological and experimental parameters for the evaluation of survival at three and five years after diagnosis: (2) a case-control study involving different types of tumor arising in the nasopharynx as well as in the rest of the upper respiratory tract with the aim of assessing the strength of the association between EBV and these tumors. This will include comparison of clinical, histopathological, epidemiological and experimental data between the different types of tumors observed; (3) sub-study in Western European centers in Tunis to assess EBV serology as a diagnostic tool to detect NPC in patients with cervical metastatic lymph nodes with occult primary: (4) a prospective study in Hong Kong involving the family members of NPC patients to assess the value of EBV serology as a method for early detection of the disease.

DOSE EFFECT RELATIONSHIP OF LOW DOSAGE X-RAY THERAPY TO THE HEAD AND NECK AREA

G. Dean, Medico Social Research Board, *73 Lower Baggot St., Dublin 2, Ireland*

Modan et al. showed that there was an increased mortality from certain cancers among those who had been treated as children with X-ray therapy for ringworm of the scalp (Lancet, i, 277-279, 1974). It is proposed to ascertain the mortality of those who were given superficial X-ray therapy to the head and neck area between 1928 and 1960 for acne and related conditions. Hospitals at Liverpool, Glasgow, Birmingham, Manchester, Leeds and London are collaborating in the study. The main conditions treated were acne, sycosis barbae, other skin conditions and eye conditions. It is expected that information will be obtained for about 10,000 patients treated. Follow-up will be achieved using the National Health Service Register in Southport to find deaths since the start of the National Health Service in 1948 and through the Area Health Authorities and the family doctors, to find those who are still alive in case further study is required at a later date. Both the National Cancer Register and regional cancer registers will also be checked. The study program will be completed in 1981/82.

FOOD HABITS, TOBACCO USE AND DIGESTIVE CANCER IN BELGIUM

A.J. Tuyns, Centre International de Recherche sur le Cancer, Unit of Epidemiology & Biostatistics, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France*

Mortality from gastric and rectal cancer was found to be higher in the Flemish part of Belgium than in the Wallon area. Following a study showing geographical differences in mortality from digestive tract cancer in Belgium (Acta Gastro-Ent. Belg., 40, 129-147, 1977), a case-control study is being conducted to assess whether a relationship can be found between food habits, tobacco consumption and these cancers. During 1980 and 1981 all the incident cases of digestive cancer in the northern province of East-Flanders and in the southern province of Liege (expected number : 2,500) will be interviewed. Controls will consist of a stratified random sample of 2,500 persons in comparable age groups, taken from the total population. All possible food groups and their components will be analyzed with emphasis on the previously noted differences in consumption between north and south (e.g. alcohol, saturated/unsaturated fat, fiber, smoked food).

OCCUPATIONAL EXPOSURE TO RECOGNIZED CARCINOGENS

P. Vineis, Universita degli Studi di Torino, Istituto di Anatomia e Istologia Patologica, Cattedra di epidemiologia dei tumori, *Via Santena 7, I10126 Turin, Italy*

Information on 81 chemicals of possible industrial use, considered as carcinogens for man by IARC and by the American Government Conference of International Hygiene (AGCIH) or with 'sufficient' evidence of carcinogenicity for laboratory animals according to IARC, has been supplied to the local Health Authority of Piedmont. Information for each substance included chemicals, commercial and industrial names, labelling regulations and industrial activities where the substance could be used. Using this information, workplaces where recognized carcinogens are used are identified. The aims are to introduce preventive measures and to recognize groups of exposed workers for planning early diagnosis of cancer (whenever feasible) and follow-up studies.

MORTALITY IN CANADIAN MINING COMMUNITIES

D.T. Wigle, Canadian Dept. of National Health & Welfare, Lab. Centre for Disease Control, *Tunneys Pasture, Ottawa, Ontario, Canada* K1A 0L2

The objective is to determine the extent of excess mortality, particularly male lung cancer mortality, in Canadian mining communities. A pilot study which revealed substantial excess lung cancer mortality among males in three mining communities will be extended to include about 85 mining and 85 non-mining communities. Direct and indirect age-adjusted mortality rates by sex and cause will be calculated for the mining communities using the non-mining communities and Canada as reference groups. A case-control analysis of occupation will be performed for male deaths due to lung cancer (cases) and other causes (controls) in the mining communities.

STOMACH CARCINOMA IN A-BOMB SURVIVORS OF HIROSHIMA AND NAGASAKI, 1950-1977

T. Yamamoto, Radiation Effects Research Foundation, Dept. of Pathology, *5-2 Hijiyama Pk., Minami-ku, Hiroshima 730, Hiroshima, Japan* (02224)

A histopathological review will be made of stomach carcinoma cases observed in a defined population in Hiroshima and Nagasaki during 1950-1977. This population, the Extended Life Span Study sample, consists of some 100,000 persons, of whom 3/4 were in the cities at the time of bombing, whose permanent address was in or near the cities. The sample includes about 9,000 persons who were less than 2.5 km from the hypocentre at the time of bombing. Autopsy and surgical material and the relationship of stomach carcinoma incidence and histological characteristics to A-bomb radiation dose will be investigated. This is an extension of a study published in J. Radiat. Res. 19,213-227, 1978. Data are now being analyzed.

EPIDEMIOLOGY OF LYMPHOID TUMORS IN THE NORTH WEST REGION OF ENGLAND

J.H. Youngson, University Hospital of South Manchester, Dept. of Epidemiology & Social Research, *W. Didsbury, Manchester M20 8LR, England, United Kingdom*

The aim of the study is to determine retrospectively the incidence of lymphoid neoplasms in the North West of England, as a whole and by subtype, to characterize each group and sub-type demographically; to search for etiological factors with especial emphasis on possible genetic factors; to assess trends in survival on a regional basis: to look for trends in incidence with time; to assess the accuracy of cancer registry data with a view to improving this. The study is designed to cover all cases of lymphoid leukemia (acute and chronic) and non-Hodgkin lymphomas occurring in patients resident in the North West Regional Health Authority area from 1 January 1968 to 31 December 1979. The population area is approximately 4.5 million and it is expected that this survey would cover 2,608 cases of lymphoma and 1,400 cases of leukemia.

CHORIONEPITHELIOMA AND GYNECOLOGICAL DRUGS

S. Yuasa, Inst. of Public Health, Dept. of Epidemiology, *4-6-1, Shirokanedai, Minato-ku, Tokyo 108, Tokyo, Japan*

The number of deaths from chorionepithelioma in Japan from 1947 to 1976 was 6,432. Annual trends are being compared with those for live births, stillbirths (spontaneous and artificial), abortion, and production of vaginal contraceptive chemicals containing mercury, using data published officially by the Japanese government.

INCIDENCE AND GEOGRAPHICAL DISTRIBUTION OF CHILDHOOD LEUKEMIA IN THE NETHERLANDS 1972-1980

G.E. Van Zanen, Stichting Nederlandse Werkgroep Leukemie bij Kinderen, *Dr. van Welylaan 2 P.O. 60604, c/o Juliana Kinderziekenhuis, Hague, Netherlands*

Since 1972 more than 95% of all new leukemia cases in children have been registered. This was done primarily to enroll new patients in clinical trials. In all the patients the Dutch Childhood Leukemia Study Group (DCLSG) has, as a central reference laboratory, confirmed the diagnosis on bone marrow aspirates, using the FAB (French-American-British Cooperative Group) classification. This patient material will now be analyzed in order to obtain a geographical map of incidence and distribution. Additional data will be obtained. The 'map' can be used to study relationships between environmental factors (air pollution, quality of drinking water, etc.) and leukemia incidence. Any possible clustering of cases will be traced.

EPIDEMIOLOGY OF LIVER CANCER IN KARACHI

S.J. Zuberi, Jinnah Postgraduate Medical Center, Pakistan Medical Research Council, *Karachi 35, Pakistan*

Approximately 50 new cases of liver cancor are seen in the Jinnah Postgraduate Medical Center each year. Data collected include family history, place of birth, place of longest stay, past history of liver disease and cancer in the family, liver scan, needle biopsy and screening for hepatitis B antigen. Three controls for each case will be randomly selected after matching for age from the 300-400 patients with other liver diseases treated yearly in the Center, for whom the same data are collected.

CORRELATION BETWEEN HODGKIN'S DISEASE, NUMBERS AND INCIDENCE OF BOVINE LEUKEMIA IN FIVE EUROPEAN STATES

G. Mititelu, Agricultural School, Dept. of Breeding, *M. Kogalniceanust. 3, 6575 Husi, Romania*

In a previous study in males from ten countries positive correlations were found between per capita consumption of dairy products and incidence of human leukemia-lymphoma, r equals 0.80 for multiple myeloma, r equals 0.71 for lymphoid leukemia, r equals 0.62 for lymphosarcoma and r equals 0.53 for Hodgkin's Disease. The present study is seeking correlations between the incidence of Hodgkin's Disease and the number of bovine populations as well as the incidence of bovine leukemia in five countries (Denmark, Sweden, Norway, Finland and German Democratic Republic) for the 1968-1972 period, using data from 'Cancer Incidence in Five Continents', Vol. III, 1976 and 'Animal Health Yearbook', FAO, WHO, OIE for the same period.

3.1982,

DECISION MAKING ON MASS SCREENING FOR CANCER

J.D. Habbema, Erasmus University of Rotterdam, Dept. of Public Health & Social Medicine, *Wytemaweg 2A, P.O. Box 1738, 3000DR Rotterdam, Netherlands*

Policy decision about mass screening for disease are surrounded with a lot of uncertainty, and with contradictory opinions about the usefulness of screening. Quite a few factors are relevant in predicting the effects of mass screening. Among these are prevalence, incidence and mortality from the disease; sensitivity, specificity and acceptability of the screening test; attendance at the screening program, especially of high-risk groups; the natural history of the disease, the duration of the preclinical stage, and the prognosis of each stage; the change in prognosis when the disease is treated at an early stage, etc. To take account of all these factors and known interactions is impossible. Therefore, in this project stochastic decision models are developed, which have as their input assumptions about all the relevant factors, and as their output estimates of the effects of mass screening on morbidity, mortality, life-years, medical consumption, etc. These models will be implemented in a computer program and will be tested in the years to come on a number of cancer sites. The model is intended to be general, and should be applicable (with slight adaptations) to all sites of neoplasms for which screening is considered.

3.1983,

ENVIRONMENTAL, PERSONAL AND SOCIO-ECONOMIC FACTORS IN HEMATOPOIETIC SYSTEM NEOPLASMS (HSN)

E. Quiroga Micheo, Grupo Argentino Cooperativo de Estudios Epid. en Hematologia, *Las Heras 1895, 1127 Buenos Aires, Argentina*

In a descriptive epidemiological study carried out in Argentina, high rates and clusters of lymphomas and multiple myeloma in zones with arsenical water were observed. A case-control study carried out on 603 case-control pairs shows: (1) no differences with regard to personal contact with cancer or HSN patients, (2) higher occupational exposure to petroleum and its products, particularly in cases of acute non-lymphocytic leukemia, (3) a greater exposure to petroleum (especially in myeloproliferative disorders and Hodgkin's disease) and insecticides (especially in acute leukemia and myeloproliferative disorders) in cases, (4) cases living in the Greater Buenos Aires area had more dogs and other animals in their homes; (5) more cases, in particular acute lymphocytic leukemias, had a simian or Sidney fold. (No differences were observed in other personal factors: mongolism, congenital abnormalities, thymoma, neoplasms, allergy, tonsillectomy, appendectomy, tuberculosis, syphilis, brucellosis, BCG, chloramphenicol, phenylbutazone, number of X-rays, etc.); (6) the socio-economic stratification was similar in both groups. This study will be extended with the aim of measuring the degree of exposure to environmental factors. A cohort study to compare the incidence of hematopoietic system neoplasms in occupations connected with expcsure to petroleum with that of non-exposed persons is planned.

EPIDEMIOLOGICAL AND ETIOPATHOGENIC STUDY OF TUMORS OF SEROUS SURFACES

A.F. Donna, General City Hospital of Alessandria, Institute of Pathology, *Via Venezia 18, Alessandria, Italy*

During a survey of mesotheliomas in the district of Alessandria with special regard to their relationship with exposure to asbestos, a preponderance of these tumors was reported in people living in the countryside. Occupational histories obtained from these patients and/or their relatives and environmental surveys do not indicate any relationship between these tumors and exposure to asbestos. The object is to establish whether some chemicals (nitrogen and cyanide organic compounds), widely used in the Alessandria countryside, are carcinogenic in the serous membranes. This hypothesis is being assessed, at the same time, by a middle-term treatment of mice, and the mutagenic properties of the chemicals may also be examined.

EPIDERMOID AND SMALL CELL CARCINOMAS OF THE LUNG - OCCUPATIONAL DISTRIBUTION AMONG THE WORKING POPULATION OF THE RHONE-ALPES AREA

J. Mouriquand, Universite de Grenoble, Faculte de Medecine, Laboratoire d'Histologie, *38700 La Tronche, Grenoble, France*

Epidermoid and small cell carcinomas are the main contributors to the recent increase in lung carcinomas, although the clinical course and the histological aspects of the two are quite different. Potential risk factors for lung cancer have been defined mainly within factories where the working population was submitted to defined substances (chrome, nickel, etc.), and few studies have examined the general working population. This retrospective study is based on 585 cases of epidermoid carcinoma and 200 cases of small cell carcinoma of the lung. Patients were classified according to their occupation and the age at occurrence of the disease. Occupational distribution and age groups were correlated with a cohort of non-cancer patients with lung diseases for whom cytological sputum specimens were sent to the laboratory, and with the professional distribution of the active population of the same area as obtained from the 1975 census.

EPIDEMIOLOGY OF CHILDHOOD MALIGNANCIES IN JAPAN

T. Hirayama, Ministry of Health & Welfare, Epidemiology Div., *Tsukiji 5-1-1, Chuo-ku, Tokyo 104, Tokyo, Japan*

Patterns of occurrence of childhood malignancies in Japan are being studied in relation to selected risk factors based on data from nationwide registration. A total of 10,575 children (5,951 males; 4,624 females) under age 15 were registered between 1969 and 1977. Malignancies included leukemia (4,607), malignant lymphoma (750), neuroblastoma (1,002), Wilms' tumor (485), liver tumor (230), retinoblastoma (892). Age-specific incidence rates were calculated for each. When compared with vital statistics figures for all Japan, maternal ages had little or no influence, but significant risk elevation was noted under age three with increase in weight at birth, for leukemia, neuroblastoma, Wilms' tumor, testis tumor, and teratoma. Abdominal radiation exposure during the later part of pregnancy was noted to enhance leukemia risk in those children when compared with 1,011 controls of similar age. Down's syndrome was frequent in leukemia cases under age three and many cases of congenital malformation, including seven cases of hemihypertrophy, five of aniridia, six of congenital heart disease, were recorded co-existent with Wilms' tumor. The mean ages for retinoblastoma were five, six and seventeen months for bilateral, unilateral with family history, and unilateral without family history cases respectively. Analysis continues.

ESTABLISHMENT OF HOSPITAL-BASED CANCER REGISTRY ACCORDING TO THE RECOMMENDATIONS OF WHO

P.A. Carda, Inst. Nacionale de Oncologia, *Ciudad Universitaria s/n, Bartolome Cossio, Madrid 3, Spain* (02222)

Epidemiological and clinical data are being registered for cancer patients treated at the National Inst. of Oncology (about 700-750 per year), including sex and age of the patient, tumor site and stage, and type of treatment as well as family and environmental data. Patients are clinically followed-up each year. The data are used for correlation studies, mainly between clinical stages, types of treatment and survival and are compared with data from other Spanish and national (chiefly European) hospital-based registries.

ETIOLOGY OF CERVIX CANCER

S.P. Jain, J.K. Cancer Inst., Surgery Chemotherapy Pathology & Research Unit, *G.T. Rd., Kanpur 208002, Uttar Pradesh, India*

Cervix carcinoma has the highest incidence among malignant disease encountered at J.K. Cancer Institute, Kanpur. On an average 2,000 new patients are seen annually. More than 95% of the patients are of very low socioeconomic level. All have poor obstetrical histories, a large number of pregnancies and a serious offensive vaginal discharge for 20-30 years before the onset of cervix cancer. Data on socioeconomic status, number of pregnancies, vaginal discharge (including culture), cervical smear, colposcopy examination, etc. will be correlated statistically for both cervix cancer cases and women with vaginal discharge but no cancer. It is proposed to study about 200 cases per year. Emphasis will be on study of offensive discharge and its relationship to changes in the cervix.

EVALUATION OF CERVICAL CANCER SCREENING

T. Shigematsu, Fukuoka University, School of Medicine, Dept. of Public Health, *34 Nanakuma Nishi-ku, Fukuoka City 814, Japan*

In Japan cervical cancer screening has been carried out extensively, but no adequate evaluation of its impact has been made. This study aims to evaluate the effect of screening, and to establish the duration of carcinoma in situ and the optimal screening interval by introducing an intensive program in the Dogo district, the biggest of the Oki Islands, with a female population of 10,000, using the Dozen district in the same islands, with a population half that of the study area, as a control. The population at risk has been registered and its movements are checked and the register updated yearly. Screening is done by gynecologists and with a mobile unit using colposcopy. It is hoped to screen more than 90% of the population at risk in five years and to follow them for 10 years. Screening data are arranged according to the register, copies of death certificates are collected and a survey of cervical cancer patients done both in the area and at the hospitals in the surrounding area. The screening data and incidence, prevalence, mortality and end results in diagnosed cancer patients will be analyzed. A similar program is being carried out in another town in the mountain area of the same prefecture. The total female population included in the two programs is about 15,000.

EXPERIMENTAL BREAST CANCER SCREENING

J.H. Hendriks, Katholieke Universiteit Nijmegen, Dept. of Diagnostic Radiology, *Erasmuslaan 4, Nijmegen, Netherlands*

The experimental breast cancer screening project in Nijmegen, The Netherlands, was started in 1975. All women born before January 1940 and living in the city of Nijmegen are invited to participate and the third screening will be completed in 1981. Single view film mammography is used, with an average tissue dose of 0.1 R to each breast. There is no clinical examination. About 10,000 women a year are screened at two year intervals. The total number of women in the study is 24,000. Breast cancer incidence and mortality data for the city of Nijmegen have been collected from 1970. The impact of the present screening program on these is being evaluated and the prevalence/incidence ratio, the age distribution of prevalent cases and the estimated lead time will be analyzed. Differences in growth rate between cancers found by screening and those found in the interval between screenings will be calculated. Pathological and morphological characteristics of invasive and non-invasive cancerous lesions of the breast, diagnosed at and between the screening examinations, are examined.

HOSPITAL CANCER REGISTRY OF BOLLATE

P. Canevini, Caduti Bollatesi Hospital, Dept. of Pathological Anatomy & Histology, *Via Piave 2, 20021 Bollate-Milano, Italy*

A cancer registry allows epidemiological evaluation of tumors and specification of carcinogenic hazards, and, when hospital-based, provides the best source of information with regard to diagnostic certainty. The objectives of the present study are to (1) evaluate the average annual cancer incidence in the population residing in three cities near the hospital (about 70,000 inhabitants), (2) compare the average annual incidence between two four-year periods (1973-1977 and 1977-1981), (3) follow-up different types of cancer patients, and (4) identify cancer risk factors in occupation. Data on the resident population were obtained from municipality offices, and information on work activities carried out in factories was supplied by the medical offices in the area. 97% of cancer diagnoses were accompanied by histological, cytological or autopsy material. For each patient date of birth, place of residence, occupation, date of first diagnosis of neoplasia, clinical stage and therapy used, date of death, and registry number of biopsy, cytological or autopsy examinations are recorded.

IMMUNOLOGICAL CRITERIA IN THE DETECTION OF HIGH OCCUPATIONAL CANCER RISK AMONG TEXTILE WORKERS

T.A. Korosteleva, N.N. Petrov Inst. of Oncology Research, Laboratory of Experimental & Clinical Oncoimmunology, *Leningradskaja St. 68, Pesochny 2, Leningrad 188646, Russia, Union of Soviet Soc. Republics*

The purpose is to examine textile workers handling direct dyes containing benzidine and beta-naphthylamine. The workers have been divided into 3 groups according to extent and duration of exposure. The following immunological tests have been used: (1) determination of benzidine as haptene in the blood serum of workers, splitting of the direct dyes by specific rabbit immune serum; (2) determination of an endogenous carcinogen, the metabolite of tryptophane-3-hydroxyanthranilic acid (3HAA), using specific rabbit immune serum in immune diffusion in agarose as a criterion of disturbances in tryptophane metabolism. Such disturbances have frequently been observed in patients with cancer of the urinary bladder and some other sites (breast, lung); (3) determination of the index of phagocytic activity of blood neutrophils as related to specific and non-specific factors. Particles of activated carbon, loaded by benzidine- and 3-HAA -azoproteins, were used as specific factors, and staphylococcus aureus as a non-specific factor; (4) determination of blast transformation of peripheral leucocytes to PHA and benzidine- and 3-HAA-azoproteins. The blood of non-exposed workers and healthy donors was used as a control.

3.1997,

MALIGNANT NEOPLASMS OF FEMALE GENITAL ORGANS

S. Boonyanit, Mahidol University, Siriraj Hospital & Medical School, Dept. of Obstetrics & Gynaecology, *2 Prannog Rd., Bangkok 7, Thailand*

The study will describe trends in mortality from gynecological cancer in Thailand between 1970 and 1980, and incidence data collected by cancer registration since 1970. The data will permit study by area of residence, occupation, race, socioeconomic status, drugs used, customs, infections, and virus lesions in the genital tract. A retrospective case-control study of the role of estrogen therapy, particularly ethinyl estradiol, in the etiology of endometrial cancer is being undertaken on some 100-150 cases. Controls are non-cancer patients matched for age, parity, race and environment. Data on physical characteristics, obesity, diet, diabetes and other factors are obtained from cases and controls, using records of interviews and direct contact by home visits or correspondence.

PROSPECTIVE STUDY TO DETERMINE HIGH-RISK GROUPS FOR LUNG CANCER

E. Abraham, Fovarosi Bajcsy-Zsilinszky Korhaz Tuedogondozo Intezet, *10 Kobanyai ut 45, Budapest, Hungary*

Screening of the population between the ages of 40-74, both sexes, in an industrial area of Budapest with 87,000 inhabitants was started in 1968 with the aim of early detection of pulmonary diseases. Between 1975-1978, at the time of screening, supposed risk factors for lung cancer: smoking, occupational exposure, chronic respiratory complaints, fibrotic lung lesions, were determined in about 30,000 persons, 90-97% of the population group concerned. The incidence of lung cancer in the risk-free population and in the persons with several risk factors shows a significant difference at the first evaluation after three years. On the basis of chronic respiratory complaints, a high-risk group of around 9,000 people has been selected and respiratory function examinations are now taking place and will continue until 1982, together with immunological examinations. Analysis and mathematical weighting of the connection between the incidence of lung cancer and the different risk factors will be made by computer after an observation period of five years.

OVARY NEOPLASMS

S. Boonyanit, Mahidol University, Siriraj Hospital & Medical School, Dept. of Obstetrics & Gynaecology, *2 Prannog Rd., Bangkok 7, Thailand*

Ovarian cancer has a relatively high frequency which is increasing rapidly. It ranks second in frequency among neoplasms of the female genital tract and as a cause of death among gynecological patients. An important problem is its asymptomatic course which entails a late diagnosis, high mortality rate, and inadequate results in therapy. The purpose of this study is to determine incidence, prevalence and mortality rates for ovarian neoplasms for the period 1970-1980. All new cases of ovarian cancer by year, period, district and age-group for the area of Bangkok and the provinces in the center of Thailand are included. The Thai people, the Chinese minority and other groups including Vietnamese, Cambodians, Moslems, and Indians will be studied. The influence of abortion, fertility, number of marriages, divorce rates, socioeconomic status and the effects of changes in the age distribution of the female population on the incidence rate in different districts, especially among people in industrial and agricultural areas and also among people from affluent residential districts, are being assessed. Occupation, heredity, drug intake, personal habits, culture, history of cancer among ancestors, and transsexual frequency are also studied.

PORTUGUESE STUDY GROUP OF SIDE-EFFECTS OF THORIUM DIOXIDE

L.C. Cayolla da Motta, National School of Public Health of Portugal, *Ave. Padre Cruz a Telheiras, 1699 Lisbon Codex, Portugal*

Of 2,436 individuals who have received Thorotrast (a colloidal suspension of ThO2 used as intravascular radiological contrast medium) in Portugal, mostly between 1930 and 1950, 1,244 (51%) have been traced and followed up, as have 924 of 2,086 (44%) of a control group, injected for the same purpose with non-radioactive contrast material. Of the 955 deaths to 31 December 1976 among Thorotrast cases, 16 died as a direct result of the consequences of local granulomata developed from drug spillage around blood vessels (cervical granulomata in 15 cases), 137 from malignant tumors (of which 6 developed on the edge of local granulomata, 87 being primary tumors - 32 with complete histological confirmation - including 18 hemangioendotheliomas, 4 biliary duct carcinomas, 8 carcinomas of the stomach, 5 of the bronchus and lung, 2 of the larynx, 5 primary bone tumours, and 20 other localizations), 23 died from fatal blood dyscrasias (12 of which were leukemias, mostly acute and myeloid in type), and 27 from liver cirrhosis (actually a particular form of liver fibrosis). Of the 656 control deaths only 15 were caused by malignant tumors (including 4 stomach carcinomas, 1 bronchus, 1 larynx, a 1 probably primary liver tumor); there were no deaths from leukemia or other fatal blood diseases among controls and only 6 deaths were attributed to liver cirrhosis. Statistical analysis of data has shown that the number of observed deaths from malignancies particularly primary liver, bone, bronchus, and larynx tumors, and leukemia- and from liver cirrhosis in the Thorotrast cases is significantly (0.05) higher than among controls and also higher than the expected corresponding figures in the general Portuguese population. Follow-up of the remaining 300 or so patients and 300 controls will be undertaken as soon as funds are available. Results are expected to contribute, by extrapolation, to a better knowledge and understanding of the human effects of continuous low dose radiation.

NATIONAL PEDIATRIC REGISTRY (POPULATION-BASED)

J.M. Ford, Health Commission of New South Wales, Central Cancer Registry, *P.O. Box K110, Haymarket, Sydney, N.S.W. 2000, Australia*

The National Pediatric Registry was established by the Pediatric Group of the Clinical Oncological Society of Australia (of the Australian Cancer Society) in 1976, to collect and collate incidence data from January 1977, for all pediatric cancers (0 to 14 years) for all States in Australia. This is the first national collection of cancer incidence statistics. Notification of cases is voluntary, and is supervised in each State by a co-ordinator who is a member of the Pediatric Group of the Clinical Oncology Society of Australia. The notifications are forwarded to the Central Co-ordinator, who is the Registrar of the New South Wales Central Cancer Registry. The data are processed parallel with the New South Wales cancer data and a separate file is maintained. Cancer incidence by site, age, sex, cell type, country of birth of the child and his parents and grandparents, racial origin, and geographical location of the patient is currently being analyzed. The first of a series of reports is to be published in 1980.

THE SWEDISH TWIN REGISTRY STUDIES

L.T. Friberg, Karolinska Institutet, Dept. of Environmental Hygiene, *Solnavagen 1, Box 60400, S10401 Stockholm 60, Sweden*

In 1961 the Twin Registry covered about 10,000 same-sexed pairs born during the period 1886-1925. The registry was expanded in 1973 to include about 15,000 pairs born in 1926-1958. The aim of the Twin Registry is to study influences of the environment on morbidity and mortality, including cancer morbidity and mortality, based on periodical matching with the Swedish Cancer Registry. The latest updating was performed during 1979. The mortality data are evaluated through a continuous follow-up of mortality within the registries. The total twin program was reported in Acta Medica Scandinavia, Suppl. 612, 1977, in 'The Interactions of Smoking, Environment and Heredity and their Implications for Disease Etiology.' The latest report concerning cancer by Cederloef-Floderus, 'Cancer Mortality and Morbidity among 23,000 Unselected Twin Pairs' (1979) dealt mainly with concordance rates for cancer of all sites and cervical cancers.

REPRODUCTIVE AND HORMONAL FACTORS IN THE ETIOLOGY OF COLON CANCER IN WOMEN

A.J. McMichael, Commonwealth Scientific & Industrial Research Org., Div. of Human Nutrition, *Kintore Ave., Adelaide, S. Australia 5000, Australia*

In view of sex hormonal influences upon hepatic cholesterol and bile metabolism, recent isolated reports of increased colon cancer risk in nulliparous women, together with the observed pattern of age-specific variations in the sex ratio of this cancer, suggest that reproductive history and exogenous sex hormone exposure may influence colon carcinogenesis. A case-control study is underway, comparing the reproductive histories of approximately 250 colon cancer cases, and 550 age-matched controls. All study subjects were women dying during 1976-77. Further, time trends in sex-age-specific colon cancer incidence and mortality, in the US, UK, Australia and New Zealand are being compared, with particular attention being paid to the untypical prolonged decline in rates in young women.

ANTICONVULSANT DRUGS AND CANCER

A.M. McLean, University of London, University College Hospital Medical School, Dept. of Clinical Pharmacology, *University St., London WC1E 6JJ, England, United Kingdom*

Animal studies have suggested that patients with epileptics taking phenobarbitone and other anticonvulsant drugs may have an altered pattern of cancer mortality, in particular a higher incidence of liver tumors. Two groups of subjects are being studied. The first consists of patients admitted to a residential center for the treatment of epilepsy, and the second of people with less severe epilepsy living in the community. For comparison with the latter group a control population of people with limb disabilities has been taken. It is envisaged to study 5,000 epilepsy patients and 5,000 controls. Cause of death is obtained from the National Health Service Central Registry, and the cancer mortality is compared with that in the general population. Preliminary results for the first group indicate a possibly raised mortality from cancers of all sites, but with no apparent increase in liver tumors, although the numbers are small. It is hoped in the future to use cancer registration data, as well as cause of death.

EVALUATION OF METHODS OF 'RESTRICTED' COHORT ANALYSIS

J.C. McDonald, University of London, London School of Hygiene & Tropical Medicine, T.U.C. Centenary Inst. of Occupational Health, *Keppel St., London WC1E 7HT, England, United Kingdom*

The aim is to develop and assess methods for the analysis of cohort data in which follow-up is restricted to subjects at work, on retirement pension or limited periods of time after leaving employment. Observations recorded in various studies of workers exposed to asbestos and other dusts are being used for this research.

Description provided by IARC and DKFZ with ICRDB/NCI support.

3.2008,
MESOTHELIOMA AND OTHER MALIGNANT DISEASE IN CHRYSOTILE ASBESTOS FACTORY WORKERS

J.C. McDonald, University of London, London School of Hygiene & Tropical Medicine, T.U.C. Centenary Inst. of Occupational Health, *Keppel St., London WC1E 7HT, England, United Kingdom*

Cohort mortality studies are being undertaken in three large, long-established asbestos plants in the USA. In two chrysotile only has been processed and in the third crocidolite and amosite also were used since 1925. The three cohorts, not yet finalized, each comprise some 5,000 persons. Those first employed from 1937 through 1959 are of primary interest but persons employed before 1937 will also be studied. In all three plants some environmental measurements are available from 1930 onwards. In one plant a detailed study has just been completed including recent fibre levels and estimates of the equivalent in fibres of past dust levels. The possibility of similarly investigating environmental measurements in the other two plants is being investigated.

3.2009,
CANCER MORTALITY AMONG PERSONS EXPOSED TO LOW LEVELS OF CHRYSOTILE ASBESTOS IN THE MANUFACTURE OF ASBESTOS-CEMENT ARTICLES

S.F. McCullach, James Hardie Industries Ltd., Occupational Health Services, *Grand Ave., Camellia, N.S.W. 2142, Australia*

At Ipoh in Malaysia a workforce exposed only to chrysotile asbestos and engaged in the manufacture of asbestos-cement products is being studied. Engineering methods changed negligibly from 1966 when the plant came into operation to the time when the airborne asbestos concentrations in the breathing zones of the workers were first measured in 1978. On this basis it is believed that in no case has any worker's exposure exceeded two fibers/ml. On a time-weighted average basis. The cumulative exposures of all present (approximately 400) and former (approximately 1,000) employees have been determined. Death Registers will be searched to discover the deaths of those who have died after leaving the workforce. Where available, hospital records will be searched and consideration given to amending the certified cause of death. Each case will be matched with a control for sex, age within five years and place of residence. Consideration of the certified cause of death in the light of hospital records will be conducted in ignorance of whether one is dealing with case or a control.

NATURAL HISTORY OF CERVICAL CANCER

G.H. Green, University of Auckland, Postgraduate School of Obstetrics & Gynecology, *P.O. Box 2175, Claude Rd., Auckland 3, New Zealand*

The aim is to ascertain whether or not cervical cancer commences in the pre-invasive form and whether or not the discovery of carcinoma in situ by cytology will decrease the rate of mortality from invasive cervical cancer in the population. The study population consists of all cases of in situ cancer diagnosed and treated at National Womens Hospital, Auckland, New Zealand, (about 150 per annum); all cases of invasive cancer (about 50 to 60 per annum) occurring in populations served by the Auckland Hospital Board (approximately 890,000 in 1978), and all cases of in situ and invasive cancer and their district of origin reported to the National Cancer Registry, Department of Health, Wellington. All clinical and sociological data relative to cases occurring in the Auckland Hospital Board area will be correlated and age-standardized incidence and mortality rates, and trends in these will be calculated for all New Zealand cases. A cytology screening index (number of smears per 1,000 population aged 20 years and over) will be used in association with these analyses.

LUNG CANCER MORTALITY IN MEN EXPOSED TO DUST

M. Haider, Universitat Wien, Inst. of Environmental Hygiene, *Kinderspitalgasse 15, 1090 Vienna, Austria*

1,630 men exposed long-term to dust (foundry workers, workers in metal, ceramics, glass, stone and other industries) and 1,630 non-exposed matched controls were registered betwen the years 1950 and 1960 for a prospective study of workmen living in Vienna, born 1910 or before. In a separate historical cohort study on asbestos cement workers the same methods are used to compare their mortality data with data from a cohort of cement workers from the same region. (Preliminary results were published in 'New approaches to risk estimation of air pollutants', Facultas, Wein, 1979.)

LEUKEMIA AND RELATED DISORDERS IN ATOMIC BOMB SURVIVORS

M. Ichimaru, Nagasaki University, Atomic Disease Inst., Dept. of Hematology, *Sakamoto-Cho, c/o School of Medicine, Nagasaki, Japan*

Approximately 80,000 atomic bomb survivors and 30,000 controls are being studied. The radiation dose of each exposed person is calculated. 150 cases of leukemia and 22 cases of multiple myeloma have been confirmed in this sample from 1945-1976. The incidence of leukemia and related disorders, relationship to dose of gamma ray and neutron, chromosome anomalies, and differences between the two cities of Hiroshima and Nagasaki have been studied. A manuscript of a paper 'Multiple myeloma among atomic bomb survivors and controls in Hiroshima and Nagaski, by dose, 1945-1976', was sent to the J. Nat. Cancer Inst. Follow-up continues.

PROSPECTIVE POPULATION STUDY ON CANCER IN COUNTY SZABOLCS-SZATMAR, HUNGARY

L. Juhasz, Szabolcs Szatmar County Hospital, Policlinic Unit, *44 Voeroeshadsereg u. 68, H4401 Nyiregyhaza, Hungary* (01937)

This study was established in 1973 with the aim of acquiring more accurate data on cancer incidence and mortality, of examining trends in cancer and other diseases. Approximately 150,000 inhabitants of County Szabolcs-Szatmar, Hungary aged over 18 were listed. Migration is checked yearly. Death certificates are included in the study only after careful revision of the data. All the data will be compared and completed with those of the County Cancer Registry. The first evaluation will be done in 1980-1981.

3.2015,
ONTARIO MINERS STUDY

J. Muller, Ontario Occupational Health & Safety Div., Special Studies & Services Branch, *4000 University Ave., Toronto, Ontario, Canada* M7A 1T7

It is known that uranium miners have an increased lung cancer risk. This study will attempt to calculate the relationship between the time course of exposure to short-lived radon daughters and the time course of excess lung cancer risk. Several control populations will be used: Ontario males, Northern Ontario males and Ontario miners who have not worked in an uranium mine. The study will also investigate cancer risks among non-uranium miners. The employment history data and coded x-ray results (silicosis ratings) from the annual medical examinations required of all active miners in Ontario are being recorded in computer files for all uranium miners and for all miners who have reported for medical examination in 1955 or later and had 5 or more years of mining experience. In the data files, there are about 16,000 men who qualify as uranium miners and about 34,000 men who meet the latter qualifications.

The employment histories and measurements of air concentrations of short-lived radon daughters will be used to make an estimate of each uranium miner's annual exposure between 1955 and 1987. From 1966 onwards exposure was estimated by the mining company. When all these data have been assembled, there will be, for each uranium miner, a record of exposure to short-lived radon daughters for each year that he was employed as an uranium miner. Information concerning deaths in the study population will be obtained by matching the personal identifying information of each miner with information contained in the Canadian Death Registry maintained by Statistics Canada. The data files will be completely assembled in the early part of 1980 and a review will be started then. The study is on-going and the data are to be reviewed regularly.

MALIGNANT OVARIAN TUMORS IN BYELORUSSIA

D.V. Nikolaeva, Gomel Provincial Oncological Dispensary, Dept. of Radio Gynaecology, *Sovietskaya 104, Gomel, Byelorussia, Union of Soviet Soc. Republics*

There has been no recent investigation into the incidence of ovarian cancer in Byelorussia. A geographical correlation study, which included data obtained from patients, has been carried out. Incidence was correlated with risk factors including chronic genital disease, surgery on pelvic organs after age 40, reproductive history and early menopause. There seemed to be differences in environmental risk factors among women over 40 in the northern compared to the southern part of the Republic. Analysis of the data continues, and it is proposed to set up a case-control study using two groups of over 1,000 age-matched controls from urban and rural populations.

PERIMENOPAUSAL ESTROGEN TREATMENT AND BREAST CANCER RISK

L.O. Thoren, University Hospital, Dept. of Surgery, *S75014 Uppsala 14, Sweden*

This prospective cohort study includes all women within a defined geographical area who during the three year period 1977-1980 have estrogens prescribed for menopausal symptoms. The final cohort will include about 25,000 women. A comprehensive mailed questionnaire enabling detailed assessment of epidemiological characteristics, of compliance and of estrogen exposure prior to the investigation is sent to a random sample of about 900 women from the cohort and to all those who develop breast cancer. All newly diagnosed cases of breast cancer in the area are reported monthly to the investigators. The breast cancer incidence in the cohort will be observed for at least five years and related to an expected incidence derived from official statistics and from the reported total incidence in the area. Calculation of relative risks will be possible for the whole material and for subgroups according to duration of exposure, preparation, dose, etc. Possible confounding is controlled using information from the questionnaire and results from recent epidemiological investigations in the same area.

INTERNATIONAL COOPERATIVE PROGRAM FOR COMPARATIVE STUDIES IN NEIGHBORING REGIONS OF AUSTRIA, CZECHOSLOVAKIA, HUNGARY, YUGOSLAVIA

H. Wrba, Universitat Wien, Inst. Fuer Krebsforschung, *Borschkegasse 8A, A1090 Vienna, Austria*

A cooperative program has existed since 1972 between Hungary and Austria in cancer epidemiology. For Austria, the Burgenland Region on the Hungarian border is of particular interest, as previous epidemiological studies have shown that stomach cancer mortality is strikingly higher there than in the remainder of Austria. Further, the neighboring regions of Hungary and Austria are particularly suitable for comparative epidemiological studies, as the ethnic origin of the population of these regions is very similar. (The county of Burgenland belonged to Hungary until 1921.)

Morbidity data for the following sites were examined from 1969 onwards - stomach, colon, rectum, lung, female breast, cervix and corpus uteri. It is intended to analyze the data and to extend the study to larger geographical area. Since February 1976 the Cancer Registry of Slovenia, Yugoslavia has collaborated in this project and provides the pertinent data for the Pomurje district which borders both Austria and Hungary. Finally, the region of Bratislava, Czechoslovakia joined the study in 1978, also with morbidity data from 1969 onwards.

LARGE BOWEL PATHOLOGY IN AUTOPSY SERIES

D.Z. Zaridze, Centre International de Recherche sur le Cancer, Unit of Epidemiology & Biostatistics, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France*

(1) The general objectives are to study and document in a comparable manner all lesions of the colon and rectum in adult autopsy series in different geographical areas with contrasts in large bowel incidence. (2) The specific objectives are to investigate and compare the prevalence, distribution and histological types of various lesions of the colon and rectum in autopsy series in certain urban and rural populations of Europe and where feasible in other geographical areas. Among the lesions studied, the greatest attention will be given to the macroscopic and microscopic features of mucosal lesions, i.e. various types of polyps. Other lesions studied will include cancer, diverticular disease, inflammatory disease and melanosis. In the case of diverticular disease, the emphasis will be on the description of the distribution and the presence of inflammation. Data have been collected from Finland, Norway and the United Kingdom with differences in large bowel cancer incidence.

MALIGNANT MESOTHELIOMA OF THE PLEURA IN MONFALCONE

C. Bianchi, Ospedale Generale Provinciale - Monfalcone, Serv. di Anatomia ed Istologia Patologica, *Via Rossini 1, Monfalcone, Gorizia, Italy*

Ship construction and refitting has been associated with high incidence of pleural mesothelioma. Monfalcone, a town of 30,000 inhabitants near Trieste, is the site of important shipyards. In the past, particularly in the period 1920-40, naval production in Monfalcone was one of the largest in the world. At present the incidence of pleural mesothelioma in Monfalcone is unknown. The aim of this study is to collect and analyze all cases of malignant pleural mesothelioma diagnosed in Monfalcone district. Occupational history and data on smoking habits will be obtained from the patient or relatives by personal interview. Special attention will be paid to asbestos exposure from occupation or other sources.

CANCER IN MOZAMBIQUE

F. Bijlsma, (No Performing Organization Reported), *Netherlands*

Data on all malignancies diagnosed in 1977 in the Central Hospital, Maputo (formerly Lourenco Marques), where the Pathology Department is the only laboratory of its kind for the whole of Mozambique, are being collected in order to establish the relative frequency of malignant tumors of all sites. Only new cases proven by biopsy, autopsy or cytological methods are included. The data will be compared with those published by Portuguese authors over the years 1956-1970. Decrease or increase in frequency will be studied in relation to age, sex and type of tumor. Special attention is given to primary carcinoma of the liver, this being the most frequent malignant tumor in males and the second most frequent in females.

CANCER EPIDEMIOLOGY IN TURKEY

N. Bilir, Hacettepe Universitesi, Faculty of Medicine, Institute of Community Medicine, *Ankara, Turkey*

In order to start a cancer education program, the relative frequency of cancer and public knowledge of cancer in Turkey will be examined. The histopathological reports on biopsy specimens from all pathology institutions and laboratories for 1977 were reviewed and cases were collected for the one-year period. According to initial results, skin cancers (including malignant melanoma of skin) and breast cancers account for more than 1/4 of all malignant tumors. All data will be grouped by age, sex, and site. The knowledge about cancer of different segments of the population (peasants, laborers, university students) will be tested by a questionnaire using the seven warning signals of WHO as a basis. The Ministry of Health and Social Security will advise on early diagnosis of cancer, cancer prevention and cancer treatment services, and some future projects will be considered.

CHILDHOOD CANCER IN ALBERTA

J.M. Birdsell, Southern Alberta Cancer Centre, Dept. of Epidemiology, *2104 2nd St. S.W., Calgary, Alberta, Canada* T2S 1S5

Files of children diagnosed with cancer and registered with the Alberta Cancer Registry during the past 10 years are being reviewed. In addition to descriptive statistics on incidence and mortality by age, sex, site, and histology, this study will provide information on survival rates. Variables which might provide leads to etiological factors include occupation of father, place of birth and/or residence, reproductive history of mother, presence of congenital malformations, and family history of cancer. The total number of childhood cancer cases diagnosed in Alberta for the period 1968-1977 was 543 (0-14 years of age), 298 males and 245 females. The incidence of childhood cancer in Alberta has been compared with that of other population-based registries in Manitoba, Saskatchewan, Norway, and Birmingham, UK, and with results of the US Third National Cancer Survey. However, the incidence of leukemia in Alberta male children appears to be lower than the average. Data from detailed review of files for the three-year diagnosis period, 1975-77, are being analyzed in order to assess the quality of information available. Additional information will be obtained from vital statistics registrations in the province.

GYNECOLOGICAL CYTOLOGY REGISTRY, NOVA SCOTIA

G. Bisson, Victoria General Hospital, *5788 University Ave., Halifax, Nova Scotia, Canada* B3H 2Y9

A computerized gynecological cytology registry has been designed for the Province of Nova Scotia. The objectives of the registry are as follows: (1) To provide complete and accurate information regarding the numbers and location of women being screened and the number of Papanicolaou smears being examined annually throughout the Province of Nova Scotia; (2) to provide information for use in the establishment of a province-wide quality control program in the area of gynecological cytology; (3) to provide a comprehensive province-wide system of follow-up of cases who have abnormal cytology; (4) to provide epidemiological data related to malignant and pre-malignant disease of the uterus in the Province of Nova Scotia. Data are being collected from all laboratories providing a gynecological cytology service in the Province of Nova Scotia using standardized diagnostic terminology and a standardized requisition report form. The design of the computer program will provide annual and semi-annual reports relating to the numbers of women being screened in the province by age and county distribution. Information regarding abnormal smears and subsequent colposcopy and biopsy findings are also incorporated in the routine computer printout. Since Nova Scotia has a relatively small and stable population of approximately 300,000 women at risk of developing cervical neoplasia, it is hoped that the program will provide useful information in relation to the distribution and epidemiology of this disease in this population.

CASE-REFERENT STUDY ON OCCUPATION AND LUNG CANCER

F. Berrino, Istituto Nazionale per lo Studio e la Cura dei Tumori, Epidemiology Unit, *1 Via G Venezian, 20133 Milan, Italy*

The aims of the study are : (1) to determine what proportion of lung cancer is due to occupational exposure in a highly industrialized area of northern Italy; (2) to confirm the etiological role of a number of chemicals already shown to be associated with lung cancer in humans, especially those for which the evidence is not considered sufficient, and (3) to study the risk from other chemicals and occupation. Cases will be all new lung cancer cases occurring in the population covered by the Varese Province Cancer Registry (800,000 inhabitants). Both hospital controls and population controls will be used. Subjects will be interviewed on occupational history and confounding factors (tobacco, residence history, social class). Exposure to each chemical under study will be determined from the knowledge of its occurrence in industrial processes and from the occupational history. Exposures derived from occupations may not be specific (a number of subjects will be wrongly classified as exposed) and the resulting relative risk will probably be underestimated; however, the use of non-exposed subjects as controls is expected to produce reliable estimates of carcinogenic doses. Preliminary results from a previous study are already available.

MORTALITY EXPERIENCE AMONG PAINT PRODUCTION WORKERS

P.A. Bertazzi, Universita degli Studi di Milano, Inst. of Occupational Health, Dept. of Epidemioloy, *Via San Babila 8, 20122 Milan, Italy*

The aim of the study is to assess mortality in the period 1950-1978 among workers employed in a paint production plant operating since 1949. The workers, approximately 450, at this factory were exposed mainly to chromates, benzene and asbestos. The personal records of the workers employed since the beginning of manufacture have been obtained from the factory. For each subject date and place of birth, date of entry and leaving the industry and type of work performed are available; date, place and primary cause of death will be ascertained from death certificates. The sex, age and cause-specific mortality of people living in the same city where the factory is located will be used for comparison.

PROSPECTIVE STUDY OF OCCUPATIONAL LUNG CANCER

M.F. Baganha, Universidade de Coimbra, University Hospital of Coimbra, Clinica de Pheumologia, *Coimbra, Portugal*

This is a prospective study of workers in a mine with elevated levels of radioactivity involving clinical, radiological, spirometrical, cytological (sputum) and immunological examinations every four months. The results in terms of lung cancer will be compared with those of a group of control workers, who will undergo the same examinations. Both cases and controls will be asked in detail about smoking habits.

TRENDS IN CANCER INCIDENCE

R. Dewar, Alberta Provincial Cancer Hospitals Board, Dept. of Epidemiology, *11560 University Ave., Edmonton, Alberta, Canada* T6G 1Z2

This study will examine the temporal variation in cancer incidence in Alberta over the years 1961-1977, and fit simple regression models to determine significant increasing or decreasing trends. All sites will be analyzed involving the processing of about 68,000 malignancies. These analyses form the basis of comparisons with similar studies, and will be useful for the monitoring of preventive measures, occupational studies and as a long-range planning tool.

3.2035,

SELECTION OF WOMEN AT HIGH RISK FOR BREAST CANCER

P.A. Bruzzi, Istituto di Oncologia, Dept. of Epidemiology, *Viale Benedetto XV, Pad. B, 16132 Genoa, Italy*

The objectives are to better assess the attributable risk of known risk factors, and to evaluate the feasibility of a screening project which, by identifying and screening high-risk groups, obtains a better cost/benefit ratio than the usual mass screening. About 5,000 women and 50 cases of breast cancer are seen yearly in the out-patient clinic for early diagnosis of breast cancer. About half of these are asymptomatic women who come spontaneously; clinical histories are collected from all women. Cross-sectional analysis has shown a significant association of breast cancer with known risk factors. Follow-up of the healthy women will be undertaken to analyze further the relative and attributable risk associated with these factors, alone or together. Various values of absolute risk for breast cancer will then be examined in order to estimate the level at which annual screenings are worthwhile on the basis of a cost/benefit ratio. It is intended to involve other institutions in the study in order to shorten the time needed to reach useful results.

RELATIONSHIP BETWEEN CUMULATIVE DUST EXPOSURE AND DEVELOPMENT OF ASBESTOSIS AND PLEURAL CHANGES IN ASBESTOS MINERS

I. Webster, South African Medical Research Council, National Research Inst. for Occupational Diseases, *Jcubert St. Ext., P.O. Box 4788, Johannesburg 2000, Transvaal, South Africa*

This survey, one of the projects dealing with exposure to asbestos dust, currently consists of the retrospective and prospective recording of the dust exposure on 2,000 white asbestos miners. Records are updated at intervals by the particular inspector of mines of the area. The cumulative dust exposure records are correlated with X-ray changes or, if death occurs, with the findings at autopsy. The radiological appearances are read by three readers, but checks for inter-observer error are made. Correlation of the pathological changes will start during this year and, where possible, dust will be extracted from the lungs for comparison with the dust exposure records. It has not yet been possible to include black mine workers in the survey although the conversion factors to convert the mine mean into an occupational exposure have been assessed. The employment of migrant labor makes the follow-up of the black worker difficult, but more active steps must be taken to find some way of adding this large group to the survey.

THE OXFORD PREGNANCY STUDY

N.J. Wald, University of Oxford, Radcliffe Infirmary, Cancer Epidemiology & Clinical Trials Unit, *Oxford OX2 6HE, England, United Kingdom*

This study is an investigation into the feasibility of linking antenatal serum samples to subsequent childhood cancer with a view to investigating the role of, for example, virus infection in the development of childhood cancer. Data have also been used to investigate the relationship between maternal serum alpha-fetoprotein levels and fetal neural-tube defects, spontaneous abortion, multiple pregnancy, diabetes mellitus and low birth weight. At present about 20,000 women have been recruited into the study. Children born to women in the study are identified and their National Health Service records tagged in Southport, so that in the event of cancer or death a notification will be sent to Oxford. At least one other center in Europe is performing a similar study, and with the collaboration of the International Agency for Research on Cancer the progress of different studies is periodically reviewed.

RELATIONSHIP BETWEEEN ALCOHOLIC DRINKS, HEPATITIS B VIRUS AND ALPHA-FETOPROTEIN AND PRIMARY LIVER CANCER

Y. Thongsomboon, National Cancer Inst., Planning & Statistics Section, *Rama 6 Rd., Bangkok 4, Thailand*

This is a retrospective case-control study, designed to determine whether there are asssociations between alcoholic drinks, hepatitis B virus infection and alpha-fetoprotein and the development of primary liver cancer. The cases and controls are the hospital population admitted to the National Cancer Inst. from July 1976 to June 1978. There are 27 cases and 83 controls, matched by sex and age-group. Information is obtained by personal interview. The laboratory work is performed in the Research Division of the same institute. Data have been analysed and the report is expected to be published in 1980.

THE CARCINOGENICITY FOR TRANSITIONAL EPITHELIUM OF METABOLITES OF PHENACETIN

J.H. Stewart, Westmead Hospital, Medicine, *Westmead, N.S.W. 2145, Australia*

The aim of this epidemiological survey is to determine whether there is an association between heavy analgesic consumption, in particular of phenacetin-containing preparations, and the occurrence of transitional-cell carcinoma of the renal pelvis or ureter in New South Wales. The association between analgesic abuse, renal papillary necrosis and carcinoma of the renal pelvis has been recognized sufficiently often, especially in Sweden, to suggest either that some component of analgesic powders and tablets is carcinogenic for uroepithelium, or that tissue destruction and inflammation associated with papillary necrosis in some way predisposes to the development of cancer. In New South Wales, Taylor has calculated an incidence of carcinoma of the renal pelvis nine times greater in kidneys damaged by analgesics than in those with non-analgesic inflammatory disease. At Sydney Hospital 35 per cent of cancers of the kidney and upper urinary tract seen between 1970 and 1976 were transitional-cell carcinomata, and 48 per cent of these occurred in analgesic habitues. The following methods will be used: (1) All patients aged 15 years and over reported to the New South Wales Central Cancer Registry with cancer of the kidney and upper urinary tract (ICD Codes 189.0, 189.0, 189.1 and 189.2) and females with bladder cancer (ICD Code 188.9) will be included. The study group will be divided into two, the first comprising those with transitional-cell carcinoma of the renal pelvis ureter or bladder, and the second those with renal cell carcinoma, with which analgesic consumption has not been implicated. (2) An appropriately matched (i.e. for age, sex and socio-economic status) group of control subjects will be drawn from the community using an accepted method. (3) A questionnaire covering possible occupational exposure to urinary carcinogens, smoking habits, analgesic intake and previous urinary tract disease, will be completed at interview and the data obtained coded for computer analysis.

THE PATHOLOGY AND EPIDEMIOLOGY OF GERM CELL TUMORS

H.B. Marsden, University Hospital of South Manchester, Dept. of Epidemiology & Social Research, *W. Didsbury, Manchester M20 8LR, England, United Kingdom*

This study was prompted by an increase in the incidence of these tumors, as assessed by the Manchester Children's Tumor Registry, which became significant in 1978. The pathology of all cases in this 25-year series, which include teratomas, yolk sac tumors and germinomas, has been reviewed to ensure diagnostic accuracy. The case-notes of each patient were carefully scrutinized for factors which may be of etiological importance and the mother's ante-natal records were also examined where these were available. These data are currently being analyzed. It is planned to extend this retrospective study to include cases in adults and a prospective case-control study of all cases aimed at the elucidation of etiological factors is also planned. Emphasis will be placed on determining the frequency of associated malformations and other tumors in the patients and their families and exposure to possible environmental carcinogens. Controls will be selected from the population and matched for age, sex and race.

TSH AS A RISK FACTOR OF CARCINOMA OF SOLITARY NODULES OF THYROID

M. Kapur, All India Inst. of Medical Sciences, Dept. of Surgery, *Ansari Nagar, New Delhi 110016, Delhi, India*

The risk of carcinoma developing in solitary nodules of the thyroid ranges from 5% to 25% in different parts of the world. Studies conducted so far have identified and 11% frequency in Delhi and the North of India. Some of the variability of carcinoma frequency in solitary nodules have been excised in this prospective study. Hormone levels of TSH, T3 and T4 are made routinely. Uniform protocols are maintained for recording clinical criteria, laboratory investigations and histological data. The frequency in patients coming from endemic and non-endemic areas is compared.

RISK FACTORS FOR MALIGANT MESOTHELIOMA

M. Haider, Universitat Wien, Inst. of Environmental Hygiene, *Kinderspitalgasse 15, 1090 Vienna, Austria*

Morbidity and mortality data from the Austrian cancer register on primary malignant pleural tumors are corrected and completed by query to pathologists and clinicians. So far 192,172 autopsy records have been reviewed. All authenticated cases diagnosed since 1969 in the Austrian population are being analyzed retrospectively with regard to risk factors, especially asbestos exposure. Occupational histories obtained from social insurance schemes are completed with the help of physicians, safety engineers, relatives, fellow workers, etc. In selected cases of deceased patients the dust content of the lung is analyzed. From 1969 to 1974, 116 malignant pleural mesotheliomas were certified, the majority of which had no occupational asbestos exposure. Preliminary results are published in 'New Approaches to Risk Estimation of Air Pollutions', Facultas, Vienna (1979).

SCREENING FOR CERVICAL CANCER - PREDICTING THE EFFECTS OF VARIOUS SCREENING POLICIES

J.D. Habbema, Erasmus University of Rotterdam, Dept. of Public Health & Social Medicine, *Wytemaweg 2A, P.O. Box 1738, 3000DR Rotterdam, Netherlands*

A computer program has been developed to simulate the effects of mass screening policy. This program is applied to the Dutch cervical cancer mass screening program. Special attention is paid to hysterectomies for reasons other than cervical cancer and to the large number of cervical smears that are made outside the mass screening program. Parameters describing the mortality, morbidity, natural history, screening attendance and validity of the test will be collected, either from the literature or by special studies, e.g. the number and age-distribution of smears made outside mass screening programs in Rotterdam 1976-1977, and the incidence and survival rates of cervical cancer patients. These parameters will subsequently be tested in the program in order to reproduce the cervical cancer mortality before mass screening started, and to reproduce the first findings of the current mass screening. Then, alternative screening policies will be simulated in order to compare their expected effects.

STUDIES OF BILATERAL BREAST NEOPLASMS

J.M. Elwood, Cancer Control Agency of British Columbia, Division of Epidemiology, *2656 Heather St., Vancouver, British Columbia, Canada* V5Z 3J3

Special registries of second primary breast neoplasms have been kept for all breast cancer patients seen at the major referral center in Vancouver since 1938. Information on approximately 800 patients with confirmed second primary neoplasm is being compared to that of a series of patients with unilateral breast cancer, matched by age at diagnosis, year of diagnosis, and survival over the interval between the first and second neoplasms. The analysis will (1) assess the incidence rates of second primary neoplasms in breast cancer patients, (2) compare epidemiological characteristics between women who develop the second primary and those who do not, and (3) assess the impact on survival of the development of a second primary tumor.

LIVER CIRRHOSIS AND LIVER CANCER AMONG KOREANS LIVING IN JAPAN

K. Song, Osaka University, School of Medicine, Dept. of Public Health, *33 Joan-cho, Kita-ku, Osaka 530, Osaka, Japan*

The age-adjusted mortality rates for liver cirrhosis and liver cancer among Korean males living in Osaka, Japan are 39.2 and 88.4 per 100,000 population - about three times higher than those of Japanese males. A similar difference is seen in females. The positive rate of HBsAg among the Korean population living in Osaka was examined, using data from blood donors at the Osaka Red Cross Blood Center. The positive rates among Koreans were 7.6% in males and 3.2% in females, in contrast to 2.2% in Japanese males and 1.6% in Japanese females. Case-control studies in Koreans living in Osaka are being conducted using 47 male and 13 female Korean patients with liver cirrhosis, admitted to the Kyowa hospital between January 1977 and August 1979, and sex- and age-matched controls chosen from Korean patients with other diseases. In the first study the prevalence of HBsAg in patients is compared to the prevalence in controls. The second study investigates alcohol consumption in the same groups.

CANCER INCIDENCE AMONG VINYL CHLORIDE AND POLYVINYL-CHLORIDE WORKERS

S. Storetvedt Heldaas, Norsk Hydro, Dept. of Health, *3900 Porsgrunn, Norway*

The aim is to evaluate whether workers exposed to vinyl chloride have an increased risk of developing cancers other than angiosarcoma of the liver. In a historical study, the mortality and cancer incidence among workers producing polyvinyl chloride since 1950 is followed from 1950 through 1978. A complete working history for all members, some 1,400, of the population is recorded and they are characterized according to levels of exposure. The mortality rates for similar age-groups in the Norwegian population are used to compare mortality. As reference for cancer incidence, rates for both the total Norwegian population, a local population and an internal population consisting of workers employed for a short period are being used.

MORTALITY AND CANCER DEATH AMONG CHIMNEY SWEEPS

E. Stoettrup Hansen, Kobenhavns Universitet, Faculty of Medicine, Institute of Hygiene, *Blegdamsvej 21, 2100 Copenhagen 0, Denmark*

Among the adverse influences to which chimney sweeps are exposed are excessive heat and significant amounts of chemicals in combustion products; in addition, they are subject to a severe physical strain. retrospective and prospective cohort study of the mortality pattern and, especially, the incidence of malignant neoplasms among chimney sweeps will be made. The study will include all Danish chimney sweeps (about 700 persons). A preliminary study of the Copenhagen chimney sweeps from 1958 to 1977 indicates that cancer deaths among chimney sweeps aged 40-69 years are 3-4 times as frequent as might be expected. Malignant neoplasms of lymphatic and hematopoietic tissue were found to occur as often as respiratory cancer. Pancreatic cancer, too, constituted a much higher proportion of the cancer deaths than expected. Suggestions of causal relationship between specific cancer sites and exposure to high temperatures, certain metals and certain volatile hydrocarbons will be investigated. An estimation of present day exposure will be made through examination of the hygiene conditions at the place of work.

DESCRIPTIVE EPIDEMIOLOGY OF BREAST CANCER IN ITALY

B. Terracini, Universita degli Studi di Torino, Istituto di Anatomia e Istologia Patologica, *Via Santena 7, I10126 Turin, Italy*

Piedmont (population in 1971, 4.5 million) is a highly industrialized area. A large part of its population immigrated during 1955-65 from other Italian regions, mainly from the mountain and agricultural areas of Southern Italy. An analysis is under way of the trends of mortality rates from breast cancer during 1951-76 in Italy, in the 6 provinces of Piedmont and in the city of Torino (capital of Piedmont). In addition, a survey is being carried out to estimate incidence rates in Piedmont during 1978-79. The purpose is to investigate the role of year of birth, age and place of birth (industrial North or other Italian regions) in the appearance of breast cancer. The study will also be used as a basis for planning a case-control study on the association between breast cancer and lifestyle (including nutritional) factors in Peidmont.

PROSPECTIVE COHORT STUDY ON ASSOCIATION OF PRIMARY HEPATOCELLULAR CARCINOMA (PHC) WITH HEPATITIS B VIRUS AND AFLATOXIN B1
J. Tu, Shanghai Cancer Inst., Dept. of Epidemiology, *270 Dong An Rd., Shanghai, Peoples Republic of China*
In areas where aflatoxin B1 contamination is serious, the incidence of PHC is highest among those with HBV infection. This prospective cohort study aims to clarify the role of HBV infection and aflatoxin B1 intake in the prevalence of PHC, and the synergistic action that might exist between these two factors. Fifteen thousand males over 40 years of age residing in a Shanghai suburban county will be studied. They will be divided into an active HBV infectious group and a non-infectious group according to their response to HBs Ag, anti-HBs and anti-HBc examination. The amount of aflatoxin B1 intake will be examined among 200 families selected randomly from these different groups. Personal information to be obtained includes alterations in the proportion of corn intake during the last 30 years, the method of corn storage and previous history of liver disease. The number of liver cancer cases appearing in different groups will be compared after a five-year follow-up.

3.2066,
PRIMARY LYMPHOMA OF THE SMALL INTESTINE IN TRUJILLO, PERU
P.F. Albujar, Universidad Nacional de Trujillo, Departamento de Medicina, *Trujillo, Peru* (003)
Thirty-three cases of primary gastrointestinal lymphoma have been observed over a 15-year period at two general hospitals in the city of Trujillo, Peru. They represent 0.4% of all malignant neoplasms seen during that period; 5.4% of malignant tumors of the digestive tract; and 14% of 225 nodal and extranodal lymphomas. The local distribution of the 33 gastrointestinal lymphomas is: gastric, 6; small intestine, 24; and colorectal, 3.
Primary lymphosarcoma represented 63% of all malignant tumors of small bowel. The majority of patients was male and above 40 years of age. Clinically, intestinal obstruction and palpable abdominal mass were the most common manifestations. The most common gross types were constrictive (annular) and polypoid. Histologically, all cases in this series were non-Hodgkin's, 23 were diffuse and one was modular. Involvement of lymph nodes was the most significant pathologic feature which seemed to correlate with prognosis.

LYMPHOMAS IN TRUJILLO, PERU - CLINICO-PATHOLOGIC STUDY
P.F. Albujar, Hospital Belen, Depto. Medicina, *Apartado 315, c/o Univ. Nac. de Trujillo, Trujillo, Peru* (014)
OBJECTIVE: To perform a retrospective study of lymphomas registered in the city of Trujillo, Peru, over a 10-year period (1971-1980) in order to establish clinical, histopathological and epidemiological (relative frequency, age, sex and place of residence of patients) characteristics.
APPROACH: Data will be taken from clinical histories and registered in an ad-hoc protocol. In each case, the histologic slide will be reviewed in order to determine the diagnosis in accordance with the World Health Organization's recommended classification. (Translated)

DIGESTIVE ENDOSCOPY IN GASTRIC CANCER
R. Aires Correia, Universidade Federal do Ceara, Hospital das Clinicas, Dept. of Gastroenterologia e Hepatologia, *Rua Cap Francisco Pedro s/n, Porangabussu, Fortaleza 60000, Ceara, Brazil* (017)
OBJECTIVES: To evaluate the prevalence of gastric cancer in Ceara where there are empirical indications of high incidence of this form of cancer. To perform a precise diagnosis, endoscopy and anatomopathology by gastric biopsy. To study the feasibility of early diagnosis by endoscopy.
APPROACH: In all cases of suspected gastric cancer, referral is made to the endoscopy section where that procedure is used. A flexible fiber optics apparatus is utilized. Biopsies obtained by endoscopy are analyzed histologically. Cases considered to be operable undergo surgery and the results are compared. (Translated)

ENDOMETRIAL CARCINOMA - EPIDEMIOLOGY AND TREATMENT
T.A. Salmi, (No Performing Organization Reported), *Ohio*
OBJECTIVE: In the literature, marked differences between the use of estrogens and rates of endometrial carcinoma have been found in the USA and in Finland. According to my investigation: 'Risk factors in endometrial carcinoma with special reference to the use of estrogens' (Acta Obstet. Gynecol. Scand. (suppl.) 86, 1979), no correlation was found between endometrial carcinoma and the use of estrogens; whereas in most of the investigations done in the USA such a correlation has been found. The objective of the current cancer research project is to determine the possible differences between these epidemiological studies.
APPROACH: The use of estrogens by endometrial cancer patients (American patient material) is being clarified, with special attention given to the type of estrogen used.
PROGRESS: This cancer research project is to be completed in August 1981.

BREAST SECRETION IN FINNISH WOMEN - A METABOLIC EPIDEMIOLOGIC STUDY

K. Kettunen, University Central Hospital of Kuopio, Dept. of Surgery, *Kuopio, Finland*

This investigation is a part of a cancer research project directed by Dr. Ernst L. Wynder, American Health Foundation, Naylor Dana Institute for Disease Prevention, Valhalla, New York 10595.

Epidemiologic data show major differences in breast cancer incidence and mortality between different human populations. Despite intensive scientific studies of the etiology of breast cancer, no single factor, with the possible exception of nutrition, has become evident that is consonant with the distribution pattern of the disease. Recent studies point to the content of breast secretion as a parameter which may be involved in breast carcinogenesis. It is possible that the quantity and the composition of the secretion could relate to the pathogenesis of breast cancer. The present study was undertaken to determine quantitative and qualitative aspects of breast secretion, in order to contribute to our understanding of the pattern and composition of this secretion, particularly in terms of its hormones, prolactin and estrogen. Because Finnish women exhibit an intermediate risk for breast cacer, they were selected as the study population, thereby enabling comparisons with data being collected in the United States and Japan.

VITAMIN A INTAKE AND STATUS IN SOUTHERN EUROPEAN MIGRANTS TO AUSTRALIA IN RELATION TO CANCER RISK

A.J. McMichael, Commonwealth Scientific & Industrial Research Org., Div. of Human Nutrition, *Kintore Ave., Adelaide, S. Australia 5000, Australia* (02385)

There is growing evidence, both experimental and epidemiological, that Vitamin A protects against epithelial cancers. Southern European Migrants, who have come to Australia in large numbers since 1950, are initially at low risk overall cancer mortality (stomach cancer excluded). The increased cancer risk associated with lengthening period of residence could reflect changes in both specific and general factors, e.g. the increases in colo-rectal cancer rates have been considered primarily in terms of dietary factors that directly influence the intra-colonic environment. However, it is possible that the dietary changes associated with migration - including a reduced consumption of fruit and vegetables - entail a change in Vitamin A status, with consequent general effects upon carcinogenesis. Detailed diet histories have been collected from a random sample of approximately 100 Greek, Italian and Yugoslav migrants living in Adelaide. Equivalent data are available for a random sample of approximately 500 Australian-born persons, with the same age and sex distribution. Dietary Vitamin A intake is being estimated, and, for the migrants, related to duration of stay and extent of post-migration dietary change. Blood samples are being obtained from a sub-group of the study population, for serum retinol determination.

EPIDEMIOLOGY OF BREAST CANCER AND BENIGN BREAST DISEASE IN WESTERN AUSTRALIA

N.T. Fleming, University of Western Australia, Queen Elizabeth II Medical Centre, Dept. of Surgery, *Nedlands, W. Australia 6009, Australia* (02264)

The main objectives of the study are: (1) To establish the incidence of breast cancer in Western Australia making note of the stage of disease at initial presentation, the pathologist's description, type of surgery done, and other relevant variables; (2) to establish the number of biopsies carried out per year for benign breast disease in Western Australia, noting the pathological description for each case and other relevant variables. For both aspects of the study, data will be obtained for the year 1978 only, and will be obtained from computer-stored lists of hospital admissions for treatment of breast disease, further information from pathology records and, for a few cases, requests to medical specialists for information from their patient records. There is no contact with patients in this study.

INCIDENCE OF CANCER IN WESTERN AUSTRALIA

M. Hatton, Western Australia Dept. of Health & Medical Services, Statistics Branch, *60 Beaufort St., Perth, WA 6000, Australia* (00960)

Western Australia has a diverse climate over its 1,000,000 square miles of area, and a scattered population of approximately 1,000,000. This population has remained relatively stable, making possible extensive epidemiological analysis, including long term follow-up. Cancer incidence, by site, age, sex, geographical location of patient, work history, and detailed treatment for three months following diagnosis is currently being analyzed.

MESOTHELIOMA SURVEILLANCE PROGRAM

D.A. Ferguson, Commonwealth Inst. of Health, Dept. of Occupational Health, *Bldg. A47, c/o U. of Sydney, Sydney, NSW 2006, Australia* (02454)

The Mesothelioma Surveillance Program was inaugurated on 9 July 1980. The Program was initiated for the general purposes of standardizing the diagnosis and classification and of furthering epidemiological knowledge of the disease. Particularly, it is desirable to identify potential causal agents other that asbestos, to determine the relative importance of different fiber types in causation, and to establish dose-response relationships. It is essential for example to establish whether relatively minor exposures are associated with increased risk of mesothelioma. The program has been three years in development, during which time methods and criteria have been tested and perfected on diagnosis, fiber counting in lung tissue and environmental history taking. Panels of experts from around Australia and New Zealand are taking part in all aspects of the program, which is a research project likely to extend over ten or more years. It is not a statuatory register, though it will be collaborating with State cancer registers and with the Western Australian Mesothelioma Register. Various protocol measures have been devised to meet ethical requirements.

CANCER INCIDENCE IN LA PAZ, BOLIVIA

J.L. Rios Dalenz, Registro de Cancer de La Paz, *Casilla 2801, La Paz, Bolivia* (02310)

There has been no statistical study of the frequency of malignant tumors in La Paz, Bolivia, although clinical observations indicate that some malignant tumors such as bronchogenic and colon carcinoma, are very rare while others, such as cancer of the cervix, stomach and gall bladder, are frequent. A survey to detect all cancer cases in residents of the city of La Paz, Bolivia is being carried out with the aim of establishing cancer incidence by age, sex, site and type of neoplasms. Epidemiological and clinical data on stage, treatment and follow-up are also included. The survey covers all hospitals, clinics, laboratories and other medical facilities in La Paz, as well as death certificates. This city is located 3,600 meters above sea level with a population of nearly 700,000. Results will be analyzed after a three year period, ending in 1981.

EPIDEMIOLOGICAL STUDY OF A LEUKEMIA EXCESS IN A COMMUNITY HEALTH AREA 6

G.P. Theriault, Universite Laval, School of Medicine, Dept. de Medicine Sociale et Preventive, *Ste. Foy, Quebec, Canada* G1K 7P4 (02352)

A leukemia excess in adults has been reported for 1978-1979 in a community health area of Quebec Province. This excess affects both males and females and is mainly due to non-lymphocytic leukemia. The objective is to describe the distribution of leukemia in this area over a period of ten years and try to determine the cause of the excess noted in 1978-1979, using the case-control approach. The total number of known cases to date is 225, 55 of them being in one town. In this town, two controls (one hospital patient and one neighbor) will be matched with each case and all individuals will be surveyed in order to demonstrate a possible exposure to some special agent contributing to the leukemia exess.

LUNG CANCER IN CUBA

O. Joly, Ministerio de Salud Publica, Instituto Nacional de Oncologia y Radiobiologia, Dept. of Research, *Calle 29 y E Vedado, Havana 4, Cuba* (01155)

The objective of this case-control study is to determine (1) Whether Cubans who smoke experience a higher risk of developing lung cancer than those who do not, and whether this risk varies with light or dark cigarettes, (2) Whether the histological types of lung cancer are related to type of tobacco smoked, and (3) If there is a relationship between lung cancer and the reproductive history of affected females. The expected number of cases will be about 200 women and 500 men. The study will ascertain all new cases of lung cancer that occur in a defined geographical area - the city of Havana during a certain period of time. Two age-matched controls, one hospital and one neighborhood, will be used. Uniform diagnostic criteria are assured by a committee of pathologists which will review all slides. Data are being obtained on types of tobacco used, number of years smoked, patterns of smoking, drinking habits, occupational exposure, and demographic information.

DEVELOPMENT OF ELECTRONIC DATA PROCESSING (EDP) PROGRAMS FOR DESCRIPTIVE AND ANALYTICAL STUDIES ON THE INCIDENCE OF PLEURAL CANCER

F.B. Behrendt, Aarhus Universitet, Inst. of Hygiene, *Universitetsparken, Bygn. 182, 8000 Aarhus C, Denmark* (02404)

This is a descriptive epidemiological study of pleural mesothelioma. As a result of co-operation between countries of the European Economic Community about 600 cases were registered between 1961 and 1972. The material has now been supplemented so that the number of cases amounts to more that 900. An analysis of the data will be carried out in co-operation with the Department of Datology, Institute of Mathematics, University of Aarhus, with the aim of establishing the extent and dynamic spread in time, place and population groups of this disease. At the same time the necessary EDP programs will be standardized for future use in similar studies of other diseases.

MALIGNANT LYMPHOHEMOPOIETIC DISEASE AND OCCUPATIONAL RISK

J. Fabry, Universite de Lyon, Lab. de Medecine Preventive et Sante Publique, *8 ave. Rockefeller, 69373 Lyon Cedex 2, France* (02453)

The main purpose of this study is to identify relative risks of leukemia, lymphoma and Hodgkin's disease which are significantly high for some occupational activities or exposures, whether previously suspected or not. Moreover, the study will try to assess the proportion of these malignant diseases attributable to an occupational risk. This case-control study includes 700-1,000 cases, detected over three years in a highly industrialized area; controls are chosen, after matching, from other in-patients. The survey involves detailed occupational interview, with a novel technique, and a review of this interview by industrial experts in order to identify probable occupational exposures. Statistical processing will be carried out as in case-control studies.

PRECANCEROUS LESIONS OF THE ESOPHAGUS IN A HIGH-RISK POPULATION

N. Munoz, Centre International de Recherche sur le Cancer, Division of Epidemiology & Biostatistics, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France* (02466)

A total of 523 individuals from the Cheng Guan commune of Lin County People's Republic of China was included in this study. One third had been examined by the Chinese balloon technique five years before and dysplasia diagnosed cytologically. One third were age- and sex-matched controls of the first group and had a normal esophageal cytology in the same survey. The remaining third were not included in the cytological survey five years before. For each subject a questionnaire containing basic demographic data, information on smoking, alcohol, dietary habits and symptomatology was completed, followed by physical and endoscopic examination with guided cytology and biopsies. Hair specimens were collected from all individuals for zinc analysis and blood was collected in a selected sample. Chronic esophagitis was observed in 90% of the subjects (mild 56%, moderate 28% and severe 6%). The endoscopic and histological characteristics of the chronic esophagitis are similar to those observed in High esophageal cancers incidence areas in Iran. This lesion increases in severity with age and moderate and severe degrees were more frequent in males than in females. Incontinence of cardia, as in Iran, was relatively infrequent (13%) and esophageal varices were found in 7.6% of the subjects. Dysplasia was diagnosed in 39 cases (7.5%), esophageal cancer in 10 patients (2%) and adenocarcinoma of the gastric fundus in three cases. Out of the 10 esophageal cancer cases, six were located in the cardia. The cytological and histological evaluation of these lesions is still in progress, and their possible relationship with specific nutritional deficiencies (Vitamin A, riboflavin and zinc) is being explored. If positive associations are found it will be possible to carry out intervention studies in this population. A similar epidemiological and endoscopic survey is being proposed in a low incidence area for esophageal cancer and in other high risk areas with completely different environments.

VINYL CHLORIDE IN RELATION TO MALIGNANT TUMORS

R. Flamant, Inst. National de la Sante et de la Recherche Medicale, Dept. de Statistique Medicale, *16 Bis A. Paul Vaillant Cout., c/o Inst. Gustave Roussy, 94800 Villejuif, France* (02301)

The purpose of this prospective study is to examine the relationship between vinyl chloride (VC) exposure and pathology (in particular malignant tumors) and causes of death. It will be conducted in factories producing VC (monomer or polymer). Only male workers, aged between 40 and 55 years, will be considered for study. For each worker exposed a worker never exposed to VC, of the same age (plus or minus two years), working in the same plant, will be used as a control. Both exposed and non-exposed workers will be interrogated by the same physician. The form contains some identification items (age, civil status, place of residence), information on exposure, including the whole occupational history, on tobacco and alcohol habits, and on health status. The subjects in the study will be seen yearly for four years in order to follow their health status and note possible changes in relation to VC exposure.

EPIDEMIOLOGY OF MALIGNANT MELANOMA IN THE GERMAN DEMOCRATIC REPUBLIC (GDR) AND IN THE FEDERAL REPUBLIC OF GERMANY (FRG)

H.D. Jung, Kreiskrankenhaus Kreispoliklinik, *M. Ostrowskistrasse 69, 209 Templin, German Democratic Republic* (01063)

It is legally compulsory in the GDR to report malignant melanoma of the skin and epidemiological data have been ascertained and trends established from 1955 through 1975. The 12 year period 1964 through 1975 is being analyzed in greater detail and the incidence trend calculated. Absolute figures for malignant melanoma are being calculated per 100,000 of the respective resident populations and the age-adjusted incidence established. Mortality statistics are used to investigate whether the number of deaths from malignant melanoma is on the increase and regional differences in incidence are being analyzed to serve as pointers to factors causing and favoring tumors. An attempt is to be made to calculate incidence for the FRG, where analogous geographical, racial and endogeneous and exogeneous influences should produce comparable data.

CANCER AND CARDIOVASCULAR DISEASES AMONG WORKERS EXPOSED TO FLUOROCARBONS

O. Axelson, University of Linkoping, University Hospital, Dept. of Occupational Medicine, *58185 Linkoping, Sweden* (02448)

'Freons', halogenated hydrocarbons, are widely used in refrigerators, air conditioners, as propellant gases in spray-products and as solvent in industry. The chemical structure of these compounds has some similarities with known carcinogens such as ethylene dibromide and ethylene dichloride, as well as with some anesthetic gases (especially halothane), which are epidemiologically suspected to have some carcinogenic potential. Heavy exposure might result in cardiac arrythmias as has been reported in humans after the use of medical spray-products. However, in spite of possible adverse health effects of 'freons', they are looked upon as non-toxic substances with relatively high permissible exposure levels. Since there are no epidemiological data available, a cohort study has been initiated, comprising about 600 individuals occupationally exposed to 'freons' during the 60s and 70s. Incidence and mortality from all types of cancers as well as deaths from other causes will be studied. Expected numbers of incident cases and deaths will be calculated from the national rates as provided by the Swedish National Cancer Registry and the National Registry of Causes of Death.

MAPPING AND EPIDEMIOLOGICAL EVALUATION OF DATA FROM THE SAARLAND CANCER REGISTRY

H.W. Beckenkamp, Arbeitsmedizinisches Zentrum der Berufsgenossenschaften, *Kossmannstr. 48-52, Saarbruecken, Federal Republic of Germany* (02228)

Registered cancer cases and deaths in the Saarland from 1970 to 1974 are being geographically mapped. In the first part of the study 2,400 cases of lung and bronchus cancer were analyzed in relation to incidence, geographical distribution and sites of industry and air pollution in Saarland. 370 cases of lung and bronchus cancer from the city of Saarbruecken were analyzed similarly, with the inclusion of occupation

and measurement of air pollution using chemical and physical estimations and bioindicators. 380 cases of lung and bronchus cancer in industrial agglomerations, 4,000 cases of stomach and intestinal cancer and all cases of leukemias are now being mapped for the period 1970-1974.

RED PALM OIL CONSUMPTION AND CANCER IN SALVADOR, BRAZIL

J.D. Buckley, Imperial Cancer Research Fund, Cancer Epidemiology & Clinical Trials Unit, *9 Keble Rd., Oxford OX1 3QG, England, United Kingdom* (02258)

Animal and in vitro studies have shown that vitamn A can protect variety of tissues, especially epithelial, against cancer induction. Human epidemiology has generally been consistent with this finding, but inconclusive because of the association of vitamin intake with that of many other nutrients, and with social and economic factors. This study will examine the vitamin A consumption of cancer cases and controls in Salvador, where a high proportion of the vitamin A intake of many inhabitants comes from a cooking oil, red palm oil. The oil is distinctively flavored and colored, and is used with specific dishes. Non-users of the oil receive, on average, less than the Recommended Daily Allowance (RDA) of vitamin A while regular users consume several times the RDA. All cancer cases presented at the major hospitals in Salvador will be interviewed and a blood sample taken. A hospital control, and in some instances, a neighborhood control will also be interviewed. It is expected that 2,000 cases will be seen over a two year period.

CANCER EPIDEMIOLOGY IN TANNERY WORKERS

E. Buiatti, Center for the Prevention of Social Diseases, Unit for Epidemiological Research in Environmental Toxicolog, *171 Viale Alessandro Volta, 50131 Florence, Italy* (02366)

It is known that tannery workers are potentially exposed to different carcinogens. About 4,000 tannery workers are concentrated in a small village near Florence (Italy). The purposes of this study are: (1) to define the mortality patterns of the population of the village (S. Croce sull'Arno) from 1960 to 1980; (2) to conduct a case-control study on the cancers for which an observed number of deaths higher than the expected will be found; (3) to conduct a cohort study on tannery workers for defining their cancer incidence and mortality (period: 1970-1985). The control group for the mortality data will be the Italian population and the population of another small village without tanneries. The data will be related with industrial hygiene data, mutagenesis and carcinogenesis tests, and biological tests on exposure to carcinogens, which will be programmed and conducted by other research groups.

CANCER REGISTRY OF RAGUSA

L. Dardanoni, Universita degli Studi di Palermo, Inst. of Hygiene G. DAlessandro, *Via del Vespro 133, Palermo, Italy* (02235)

Population-based morbidity and mortality studies of cancer are hampered by the unavailability or by the unreliability of official data. The institution of a Cancer Registry using methods of data collection comparable with similar registries makes it possible to study morbidity/mortality rates in different populations, and to carry out epidemiological investigations. The Province of Ragusa (population 220,000) has six hospitals and no private clinics. The crude cancer mortality rate is about 170 per 100,000 (1977). Data on cancer patients are collected in hospitals or in clinical pathology or radiology departments. An inquiry by a health visitor is made whenever possible. Mortality data are obtained from death certificates and submitted to cross check with hospital records.

CASE-CONTROL STUDY ON RISK FACTORS FOR STOMACH CANCER IN BAVARIA AND HESSE

R.R. Frentzel Beyme, Deutsches Krebsforschungszentrum, Institut fuer Dokumentation Information und Statistik, Dept. of Epidemiology, *Im Neuenheimer Feld 280, D6900 Heidelberg 1, Federal Republic of Germany* (02455)

During the last 25 years, Bavaria has shown the highest mortality rates for this cancer in the Federal Republic of Germany, whereas the adjacent region of Hesse had the lowest rates for both sexes. A case-control study is to be carried out simultaneously in both regions to study etiological factors for stomach cancer. The objectives include investigations into the influence of dietary factors, occupational exposure and psycho-social risk factors. The comparison groups for the cases in Bavaria and Hesse will consist of gastroenterology patients, other patients and neighborhood controls. The relevant information will be obtained by use of a special questionnaire and interview by trained personnel.

CANCER RISK IN NICKEL-EXPOSED WELDERS

R.R. Frentzel Beyme, Deutsches Krebsforschungszentrum, Institut fuer Dokumentation Information und Statistik, Dept. of Epidemiology, *Im Neuenheimer Feld 280, D6900 Heidelberg 1, Federal Republic of Germany* (02456)

Nickel has been found to be a potential human carcinogen for persons occupationally exposed during smelting and refining. This study is designed to investigate any conceivable cancer risk connected with exposure to nickel fumes during welding with nickel-containing electrodes. A follow-up study, starting after 1950, will determine mortality experience. Approximately 20 factories in the Federal Republic of Germany contribute a total of about 1,500 exposed persons. The comparison group is chosen from the same factories and is mainly composed of metal cutters and turners not exposed to nickel fumes. Estimates of exposure will be derived from the average use of nickel electrodes during employment and duration of employment. Smoking habits will also be assessed.

CELL TYPE DISTRIBUTION IN HISTOLOGICAL SPECIMENS OF LUNG CANCER

M. Geddes, Center for the Prevention of Social Diseases, Unit for Epidemiological Research in Environmental Toxicol, *171 Viale Alessandro Volta, 50131 Florence, Italy* (02342)

There are data supporting the fact that the distribution of different cell types of lung cancer depends also on the source of the histological specimen. This information may be useful for avoiding biases caused by the data source in epidemiological studies on lung cancer and cell types. The purpose of the study is to revise cell-type diagnoses in about 2,000 cases of lung cancer, obtained from the Institute of Pathology of Florence. The 2,000 lung cancer diagnoses are from bronchial biopsy and operation specimen series; in addition, 400 cases of lung cancer for which a cytological diagnosis using the Saccomanno method is also available will be classified in the same way. The study will also give information about the distribution of sex and age among the different histological types.

OCCUPATION AND BLADDER CANCER

C.R. Gillis, Greater Glasgow Area Health Board, West of Scotland Cancer Surveillance Unit, *520 Bilsland Dr., c/o Ruchill Hospital, Glasgow G20 9NB, Scotland, United Kingdom* (02370)

Study of a chemical factory in the West of Scotland has produced finding of an excess of six times the number of cases of bladder neoplasm than expected in the population. None of the previously demonstrat-

ed chemical carcinogens known to cause bladder cancer are in use in this factory. Detailed occupational histories of these cases have not yet shown a common internal link. The histology of these cases has been submitted to a panel of expert pathologists for confirmation of the diagnosis. The study is continuing.

CLUSTERING IN ALIMENTARY CANCER

C.R. Gillis, Greater Glasgow Area Health Board, West of Scotland Cancer Surveillance Unit, *520 Bilsland Dr., c/o Ruchill Hospital, Glasgow G20 9NB, Scotland, United Kingdom* (02460)

An investigation has demonstrated epidemicity in alimentary cancer using the population data for Ayrshire and the appropriate cancer registration data which have been shown to be sufficient for statistical analysis. Epidemicity has been found in rural rather than in urban areas of this country, and demonstrations of space/time clustering in previous years have been repeated in the same areas using data from the most recent years available. Investigations are proceeding in order to find out whether this statistical finding has biological significance.

EPIDEMIOLOGICAL INVESTIGATIONS OF RADIATION DAMAGE IN PATIENTS TREATED WITH 224RA

W. Goessner, Gesellschaft fuer Strahlen und Umweltforschung mbH Munchen, Abt. fur Pathologie, *Ingolstaedter Landstrasse 1, D8042 Neuherberg, Federal Republic of Germany* (00792)

In about 2,000 persons treated with 224Ra for ankylosing spondylitis (Bechterew's Disease) or bone tuberculosis, the effects of this particular type of radiation are being investigated. In collaboration with orthopedic hospitals the patients are subjected to follow-up examination. The results of these investigations, in particular the onset of malignant and degenerative disease and causes of death, are evaluated with a view to establishing dose-response. Further knowledge about the risk of radiation cancers in general is thus gained.

ASBESTOS AS A 'PROMOTOR' CARCINOGEN IN EXTRAPULMONARY SITES

J.R. Goldsmith, Ben Gurion University of the Negev, University Center for Health Sciences, Epidemiology & Health Evaluation Unit, *P.O. Box 653, Beersheba 84120, Israel* (02463)

The lack of organ specificity for non-pulmonary cancer in persons occupationally exposed has been noted. It is proposed to examine epidemiological evidence of: (1) increased frequency of cancer in many non-pulmonary sites and (2) alteration in leukocyte counts, in order to examine whether asbestos, like whole body radiation, may be characterized as a 'promotor' carcinogen for non-pulmonary sites.

EVALUATION OF BREAST CANCER MASS SCREENING

J.D. Habbema, Erasmus University of Rotterdam, Dept. of Public Health & Social Medicine, *Wytemaweg 2A, P.O. Box 1738, 3000DR Rotterdam, Netherlands* (02322)

The impact of breast cancer mass screening programs will be evaluated using a computer simulation approach. First, mathematical models for description of the epidemiology and natural history of breast cancer will be developed. These models should reproduce both the age-specific incidence and mortality figures, and the distribution of incidence cases over the prognostic classes at clinical surfacing. A study of the population and clinical epidemiology of breast cancer in the Netherlands will underly this modelling. Second, results from breast cancer screening projects (yield, attendance, interval cancers, etc.) will be evaluated and used for further refinement and improvement of the model: it should be able to reproduce relevant data from both screened and unscreened populations. Such a validated breast cancer screening model can be used for predictions about the results of existing and alternative screening policies. This would be of value in decision making on mass screening for breast cancer.

CARDIFF CERVICAL CYTOLOGY STUDY

B.M. Hibbard, University of Wales, Welsh National School of Medicine, University Hospital, Dept. of Obstetrics & Gynaecology, *Heath Park, Cardiff CF1 1XP, Wales, United Kingdom* (01098)

The main objective of the Cardiff Cervical Cytology Study is to evaluate screening for cervical cancer. The study is based on a defined population: all ever-married women, aged 25-69, resident within the Cardiff City area. The basic design objective was that all eligible women should be screened three times. The defined population was enumerated by house-to-house visiting, and eligible women were offered appointments for a cervical smear test at specially organized clinics. The study began in late 1065 and the first round of visiting the city finished early in 1971. The defined population numbers some 71,000 women of whom 46,000 (65 percent) accepted the offer of the test. Subsequent to the first smear women were re-called for second and third smears at two to three yearly intervals. Some 38,000 have so far had second smear and over 30,000 have had a third. The study should provide estimates of the prevalence and incidence of the various pathological states, estimates of false negative and false positive error rates. Death and registration rates for invasive cancer in the Cardiff City are are being monitored.

3.2107,
IDENTIFICATION OF HIGH RISK FACTORS FOR BREAST CANCER IN PATIENTS WITH MAMMARY GLAND FIBROADENOMATOSIS

E. Hint, Ministry of Health of the Estonian SSR, Inst. Eksper. i Klin. Medit., Dept. of Clinical Oncology, *42 Hiiu St., Tallinn 200016, Estonian S S R, Union of Soviet Soc. Republics* (02344)

Epidemiological data have been collected by means of a special punch card, including 15 questions about high-risk factors for breast cancer (hormonal, genetic and environmental), and various breast diseases have been diagnosed in the breast screening program (10,000 women) carried out in the Estonian SSR from 1974-1980. The data obtained will be analyzed to find out: (1) whether there is an association between high-risk factors for breast cancer (increased age at first delivery, postponed natural menopause, family history of breast cancer, acute mastitis, breast trauma, etc.) and mammary gland fibroadenomatosis and (2) whether it is possible to identify the patients with precancerous mammary gland diseases ('cystic' and 'ductal' histological types) by high-risk factors. The study will be carried out in three groups of patients: (1) 500 women with mammary gland fibroadenomatosis (histological verification), (2) 500 women with mammary gland fibroadenomatosis (by mammography), (3) 1,000 women with no evidence of breast lesions (control group).

EVALUATION OF MASS SCREENING FOR STOMACH CANCER

S.N. Hisamichi, Miyagi Cancer Society, Cancer Detection Center, Dept. of Gastroenterology, *Kamisugi 6-chome, 2-81, Sendai 980, Japan* (02412)

Among all cancer deaths in Japan, mortality from cancer of the stomach ranks first. Since 1960 mass screening programs have been conducted in many places in Japan. 3.6 million people were screened in 1978. The major objectives of the study, which is supported by the Ministry of Health and Welfare of Japan, are to evaluate the gastric mass survey program and to establish the most effective screening methods. The evaluation will include epidemiological factors taking into account sampling bias or patient self-selection bias, natural course and survival rates, technological points such as sensitivity, specificity, false negative rate and predictive value, and post-benefit analysis.

3.2110,
LONG-TERM SPATIAL ANALYSIS OF CANCER MORTALITY IN RELATION TO DEMOGRAPHIC AND ENVIRONMENTAL FACTORS

W. Jedrychowski, Akademia Medyczna w Krakowie, Inst. of Social Medicine, Dept. of Epidemiology, *Ul. Kopernika 7, 31034 Cracow, Poland* (00336)

The spatial analysis of mortality due to malignant neoplasms in the population of Cracow will cover the ten-year period 1974-1984. The city of Cracow has over a million inhabitants and its four districts differ in regard to degree of air pollution, smoking habits, fertility and other social and environmental factors. The aim of the study is to make a comparison between mortality from malignant neoplasms in the four districts. Death certificates taken from the statistical office on a monthly basis have been used in the analysis of malignant neoplasms. Cancer mortality data are analyzed by sex, place of residence and primary site. Age-specific and age-adjusted rates are computed for the total population and for each district. Until now, data covering the five years 1974-1978 have been collected and are currently under analysis. The pilot study done for the year 1974 has shown that the most frequent causes of death in Cracow by sex were lung carcinoma in men and breast carcinoma in women. The highest age-adjusted rates were in the city center where the fertility rate was low and the level of atmospheric pollution, tobacco consumption and the proportion of working-class population appeared to be high.

AUCKLAND BREAST CANCER GROUP - BREAST CANCER SURVEY

R.G. Kay, Auckland University, School of Medicine, Dept. of Surgery, *P.O. Box 2175, Auckland, New Zealand* (01417)

The purpose is to study the epidemiology of breast cancer in a multi-racial society in New Zealand. This comparison of case characteristics is both between races and within a race. The controls for the latter are 1,000 women attending general practices in Auckland, New Zealand. They will be matched by age and locality with the breast cancer cases. An average of 280 new cases of breast cancer per annum occur in Auckland. importance is attached to socio-economic groups, height-weight ratios, diet, parity, history of contraceptive practices and previous breast disease. High risk families in Caucasian and Polynesian communities are under review.

MORTALITY AND CANCER MORBIDITY AMONG SWEDISH CADMIUM EXPOSED WORKERS

T.E. Kjellstroem, Auckland University, School of Medicine, Dept. of Community Health, *P.O. Box 2175, Auckland, New Zealand* (02276)

Certain epidemiological data indicate that occupational exposure to cadmium may increase the risk of cancer, especially cancer of the prostate. In a cohort study the mortality and cancer morbidity among about 1,000 workers exposed to cadmium for more than one year will be compared with a Swedish age-adjusted average, and with a control group of workers from another plant. The cohort of exposed workers will be made up from three different plants, one cadmium-nickel battery assembly plan and two cadmium-copper alloy plants. Workers employed 1945 or later will be included in the study.

3.2114,
HORMONAL ASPECT OF ENDOMETRIAL CANCER

M. Kodama, Aichi Cancer Center Research Inst., Lab. of Chemotherapy, *81 1159 Kanokoden Tashirocho, Chikusa-ku, Nagoya 464, Aichi, Japan* (02419)

Case-control study is being carried out in an attempt to clarify the etiological relevance of steroid metabolism to endometrial cancer. Steroid data for 24 cases are being compared with those for 55 controls matched for age (post-menopausal). Results so far obtained indicate that this cancer is associated with a reduction in urinary steroids, the production of which is stimulated by the pituitary luteinizing hormone. In the analysis of the epidemiological background data for 78 cases were matched with those for one or more age-matched controls. The history of endometrial cancer patients showed a low level of reproduction, results which are in agreement with the endocrinological data. Evidence is also available to indicate that the incidence of endometrial cancer in Japan is now rising.

HORMONAL ASPECTS OF CERVICAL CANCER

M. Kodama, Aichi Cancer Center Research Inst., Lab. of Chemotherapy, *81 1159 Kanokoden Tashirocho, Chikusa-ku, Nagoya 464, Aichi, Japan* (02417)

To investigate the relation between cervical cancer and steroid metabolism a case-control study of the steroid and epidemiological characteristics of patients is under way. Patients who gave birth to their first child significantly earlier than healthy controls of corresponding age, with a similar age at menarche, showed reduced excretions of adrenal steroids including 11-deoxy-17-ketosteroids and some corticosteroid metabolites in comparison with the controls, evidence indicating that cervical cancer is associated with a maturation deficiency of the adrenal gland (arrest of adrenarche). A possible relationship between early sexual activity and arrest of adrenarche may be of etiological significance in the production of this tumor (JNCI 59: 41-47, 1977; 61: 35-39, 1978). Work continues.

3.2116,
CANCER MORTALITY IN RELATION TO DRINKING WATER IN THE NETHERLANDS

H. Kool, National Inst. for Water Supply, Laboratory of Biology, *Postbox 150, 2260AD Leidschendam, Netherlands* (02420)

In the Netherlands the Rhine and Meuse rivers provide directly or indirectly the drinking water for about one third of the country's population. Among pollutants identified in the water are several mutagenic and carcinogenic organic compounds. Recent epidemiological studies carried out in the USA indicate that there may be a possible correlation between consumption of drinking water derived from poluted surface water and elevated cancer mortality rates in man. 20 cities have been selected for a survey of organic constituents in drinking water and 19 cities for correlation studies of seven cancer sites. Selection of cities was based on the type of water source (ground or surface) and treatment (ozone or chlorine); 4.6 million inhabitants of the Netherlands, about 33% of the population of the country, are included in the study. The cancer sites considered are esophagus, stomach, colon, rectum, bladder and lung. Standardized mortality rates are being correlated to the concentration range of organic groups, i.e. Trihalomethanes, total alkylbenzenes, total chlorobenzenes, total phthalates, and specific organic compounds, i.e. chloroform, bromodichloromethane trichloro-ethene, and the hardness of the drinking water.

IMMUNOLOGICAL CRITERIA IN THE DETECTION OF HIGH OCCUPATIONAL RISK

T.A. Korosteleva, N.N. Petrov Inst. of Oncology Research, Lab of Experimental and Clinical Oncoimmunology, *Leningradskaja St. 68, Pesochny 2, Leningrad 188646, Russia, Union of Soviet Soc. Republics* (02207)

The aim of the investigation is to study immune response among textile workers exposed to direct dyes. In 1976 162 textile workers and 54 healthy controls were examined. Benzidinehapten and 3-hydroxyanthranilic acid antigen were detected in the blood serum of the textile workers using specific rabbit immune sera. The results of blast transformation of peripheral leucocytes and phagocytosis reactions and the quantitative determination of immunoglobulin levels in the textile workers' blood serum indicate disturbances in immunology arising from contact with dyes. It is hoped that these data will make possible the elaboration of immunological criteria for revealing occupational cancer risk.

CORRELATION OF AIR POLLUTION AND CANCER

I.A. Kreis, National Inst. of Public Health, Div. of Epidemiology & Regional Lab., *P.O. Box 1, 3720BA Bilthoven, Netherlands* (01501)

In this collaborative project between the International Agency for Research on Cancer and the National Institute for Public Health (RIV) correlation study between air pollution and cancer will be developed, which will exploit the unique automated system of air pollution monitoring existing in the Netherlands. The pollution data collected are such that it is possible to produce an integrated average exposure to sulphur dioxide, the oxides of nitrogen, ozone and carbon monoxide, for a large number of areas covering the entire country. The Netherlands National Vital Statistics Office will be consulted for information on cancer and other death rates, for the areas considered to be meaningful for atmospheric pollution exposures. The Automated Pathological Diagnoses Storage and Retrieval System (PALGA) has an important potential for epidemiological studies as the information about cases of cancer is based on histological diagnoses.

POPULATION SCREENING FOR BREAST CANCER BY SINGLE OBLIQUE VIEW MAMMOGRAPHY

B.O. Lundgren, Gaevle Sjukhus, Mammography Section, *S80007 Gaevle, Sweden* (02384)

The long-term effects on morbidity and mortality from screening the total female population over 39 years of age in a demarcated geographical region by single oblique view mammography are being examined. With the use of available computer-based population registries about 70,000 women have been systematically and periodically screened for breast cancer since April 1974. An efficient organization was built up with the initial aim of demonstrating the feasibility of population screening. Initial prevalence rates, interval cancer rates and repeat screening detection rates are studied to obtain information on optimum time intervals for screening. Changes in morbidity and mortality are traced. Economic, epidemiological, sociological and psychological effects are studied.

ORAL CANCER AND ORAL PRECANCEROUS LESIONS IN INDIAN RURAL POPULATIONS IN RELATION TO TOBACCO HABITS

F.S. Mehta, Tata Inst. of Fundamental Research, Basic Dental Research Unit, *Homi Bhabha Rd., Bombay 400005, Maharashtra, India* (00302)

Oral cancer is one of the most common forms of cancer in India. There is a strong belief that such cancer may be preceded by certain white lesions in the oral cavity, which are thus termed precancerous. It is known, mostly through hospital-based studies, that oral tobacco habits are associated with oral cancer and precancerous conditions. The main objectives of the present study are to (1) investigate the degree of association between tobacco habits, oral cancer and precancerous conditions and (2) elucidate the natural history of oral precancerous conditions from clinical and histological viewpoints. The study design is prospective in nature. In a first survey in 1967-1968, in five districts in different parts of India where different tobacco habits prevail, 50,00 individuals were interviewed about their tobacco habits and examined for the presence of oral precancerous conditions. Since 1969 these individuals have been followed up annually, clinically, histologically, and cytologically, for change of habits and development of oral precancerous conditions. Follow-up surveys comprising a period of 10 years have been completed. A comprehensive report of the follow-up study will be published in Community Dentistry and Oral Epidemiology.

REGISTRY OF MALIGNANT LYMPHOMAS SUSPECTED TO BE ZOONOTIC IN ORIGIN

G. Mititelu, Agricultural School, Dept. of Breeding, *M. Kogalniceanust. 3, 6575 Husi, Romania* (02283)

A registry has been established to study the possible transfer of leukemogens from various species (leukemic or not) to man. The registry is open to contributors from any country and physicians wishing to register cases or obtain additional information should contact the Principal Investigator. Data are accepted (by post) if these include: type of lymphoma, age, sex, profession, duration of animal contact expecially with pets (dogs and cats), cattle, pigs, sheep, poultry, etc., as well as diet (high or no consumption of milk, meat, eggs) and residence (urban or rural). These data will be correlated with the epidemiology of leukemia - lymphoma in animals in the relevant areas and will be statistically analyzed.

SQUAMOUS CARCINOMA OF HEAD AND NECK IN SOUTH AFRICA

M.S. McCormick, Groote Schuur Hospital, Dept. of Otolaryngology, *Observatory 7925, Cape Town, South Africa* (02521)

This study is designed to correlate genetic characteristics of patients with environmental factors thought at present to be initiators and promotors of squamous cell carcinoma (SCC) of the head and neck. The following parameters will be assessed for each patient: (1) Genetic markers, including history, ABO, Rhesus and Mn blood grouping, HLA typing to include ABC and D loci and factor Bf polymorphism. (2) Initiation of carcinogenesis in which serum of patients will be tested for the presence of Herpes Virus Tumor Associated Antigen (AG4) using passive hemagglutination test. If present this represents the inclusion of viral DNA in tumor cells. (3) Environmental factors, including geographical origin, occupational exposure, tobacco, alcohol, snuff, and a history of other diseases, e.g., syphilis. New patients attending the Joint Radiotherapy/Otolaryngology Clinic at Groote Schuur Hospital, Cape Town, with a positive diagnosis of SCC of head and neck will be studied over an 18 month period. It is hoped to study approximately 150 people in this way. Controls from matched patients with infectious or benign disease are readily available.

REFERENCE REGISTRY OF BONE TUMORS

W. Remagen, Universitat Basel, Inst. of Pathology, Bone Tumor Registry, *Schoenbeinstr. 40, c/o Kantonsspital, 4056 Basel, Switzerland* (02333)

Bone tumors are extremely rare. Reference registries are necessary in order to accumulate diagnostic and epidemiological data which cannot be obtained by single institutions. Diagnostic aid is given to all contributors, and histo-pathological, radiological, and clinical material is collected at the registry for further epidemiological and histo-pathological evaluation. The registry commenced in May 1972; to date, 2,400 cases have been registered, 450 of them malignant. The registry also serves as a central reference registry to the German-Austrian-Swiss Study Group on Tumors of the Jaw-bones. Catamnestic evaluation of osteosarcoma cases in the jaw-bones, and of the rest of the skeleton, is being carried out collecting data on age and sex distributions, localizations, radiological and histological patterns, and correlating them to prognosis.

PROPORTION OF LUNG CANCER CAUSED BY PROFESSIONAL EXPOSURE TO CHEMICAL CARCINOGENS

E. Riboli, Istituto Nazionale per lo Studio e la Cura dei Tumori, Epidemiology Unit, *1 Via G Venezian, 20133 Milan, Italy* (02427)

A number of chemicals are known as lung carcinogens in humans, such as arsenic asbestos, Bis(chloromethyl) Ether, Cloromethyl Methyl Ether, chromium, nickel, soot, tar and mineral oils. There is still disagreement about the proportion of tumors attributable to these exposures the total of cases which occur in a defined population. The purpose of this study is to measure the risk from occupational exposures in the population living in a highly industrialized area near Milano, where all economic activity is being surveyed by the local Occupational Health Service in order to identify occupational hazards. The study will give information on the possible impact of primary prevention measures on lung cancer risk. All new lung cancer cases occurring in the population under study in a three year period, about 200 cases, will be included in the study. Three hospital controls, free of respiratory diseases, will be used for each case. Interviews will be conducted to obtain information on occupational history, specific chemical exposures, tobacco consumption and social class.

EPIDEMIOLOGICAL MONITORING OF THE POPULATION OF THE SEVESO AREA IN RELATION TO TETRACHLORODIBENZO-P-DIOXIN (TCDD) POLLUTION

L. Santi, Istituto di Oncologia, Dept. of Epidemiology & Biostatistics, *Viale Benedetto XV, Pad. B, 16132 Genoa, Italy* (02474)

This Institute, in charge of the epidemiological monitoring of the population of the Seveso area, has devised a general plan of research with the following primary objectives: (1) mapping of TCDD risk in the whole area, taking into account chemical, veterinary and dermatological data; (2) identification, on the basis of this mapping, of groups with different levels of TCDD exposure; (3) mortality studies; (4) a cancer incidence study using a cancer register based mainly on hospital admission/discharge charts; (5) a birth defect register based on screening. Health Services of the area are involved in the first-stage of the screening, and a special pediatric team is in charge of reviewing cases reported by the first screening; (6) follow-up of high risk groups and control groups in order to evaluate hepatotoxic, neurotoxic, mutagenic and teratogenic effects following TCDD exposure.

SCREENING FOR CANCER DETECTION AND PREVENTION IN NORD- AND SUEDWUERTTEMBERG, FEDERAL REPUBLIC OF GERMANY

R. Schrage, Universitaets Frauenklinik, Abt. fur Praevent Gyaekol und Familienplanung, *7400 Tubingen 1, Federal Republic of Germany* (02431)

A screening program for cancer detection and prevention was started in the Federal Republic of Germany in 1971. This study investigates the results of the screening program in females. The sites studied are cervix and corpus uteri, breast, rectum, skin and urinary tract. Prevalence and incidence rates are established related to age. Screening results are checked by biopsy results. The accuracy of documentation of the screening data is also controlled and methods of improving it are studied. The low interest of the population in the screening program is also being examined.

EXPOSURE-BASED CASE-CONTROL APPROACH TO DISCOVERING OCCUPATIONAL CARCINOGENS

J. Siemiatycki, Armand Frappier Institut, Centre de Recherche en Epidemiologie et Medecine Preventive, *531 Blvd. des Prairies, Case Postale 100, Laval des Rapides, Quebec, Canada* H7N 4Z3 (02469)

Of the thousands of chemicals in the environment, only a few have at present been demonstrated to be human carcinogens. There is no human evidence one way or another for almost all of the others. The discovery of unsuspected hazards is an important public health challenge. The very large number of agents to be considered renders inadequate conventional 'one-factor-at-a-time' epidemiological study methods. A few methods have been suggested which would have the effect of scanning the occupational environment to detect hitherto unsuspected human carcinogens. Even the most sensitive of these suffers from the non-specificity of job titles in ascribing occupational exposures. A case-control type approach based on exposure histories, and not simply job-title histories, of incident cases and controls, pinpoints not only high risk occupations but also specific chemicals, and provides statistical sensitivity. Exposure histories are obtained in a two-stage process. probing interview is carried out to obtain descriptions of each of the persons' jobs. Basing themselves on technical documentation and personal consultations with expert collaborators, engineers and chemists, then scrutinize each person's work history and draw up a list of possible chemical exposures. A pilot study has shown the method to be feasible. Eligibility criteria for cases are: male, aged 35-70, diagnosed in any of the the 17 major Montreal area hospitals with cancer of esophagus, stomach colon, liver, pancreas, lung, skin melanoma, prostate, testis, bladder, kidney, and lymphoma. Two control series will be used for each site, one selected from cancer patients with other sites and another from the general population. A sub-objective is to compare results obtained using cancer controls with those obtained from population controls. In total, 1,200 patients and 400 population controls will be interviewed each year. The distribution of chemical exposures among patients having a common tumor is analyzed.

EPIDEMIOLOGY, HISTOCHEMICAL AND BIOCHEMICAL FEATURES OF COLON CANCER PRECURSORS

L. Simon, Tolna County Hospital, Dept. of Gastroenterology, *Beri-Balogh Adam 7/23, P.O.B 85, 7101 Szekszard, Hungary* (02433)

Previous morphological, biochemical and histochemical studies were performed to prove the existence of two types of chronic non-specific colitis. The genetic determination of the first type of colitis was hypothesized, and some biochemical and histochemical differential diagnostic signs established. The aim of this study is to search for correlations between these two types of chronic colitis and cancer of the colon. The incidence of colorectal polyps and colon cancer will be determined in three groups of patients, with different ethnic origins, but living in the same geographical areas and cultural conditions in a County of Hungary.

MALAYSIAN CHILDHOOD LEUKEMIA

D. Sinniah, Universiti Malaya, Dept. of Paediatrics, *Kuala Lumpur, Malaysia* (02434)

With improved socio-economic conditions malignancy is now an important cause of childhood mortality in Malaysia. Epidemiological data are needed to elucidate differences in incidence and the different ratios of lymphoid and myeloid leukemia in occidentals and orientals and the childhood and adolescent peaks in mortality from leukemia. 168 consecutive cases of leukemia in children under 15 years of age admitted to the University Hospital, Kuala Lumpur from 1967 to March 1980 will be studied epidemiologically to determine if there are any differences in incidence, clinical features, types of leukemia and response to treatment as compared with Caucasian children. The possible value of BCG immunization in conferring protection against leukemia and the risk of malignancy in family members of children with leukemia will also be examined and compared with a control group of children.

GESTATIONAL TROPHOBLASTIC DISEASE IN YOGYAKARTA AND POSSIBLE ETIOLOGICAL FACTORS

Soeripto, Gadjah Mada University, School of Medicine, Dept. of Pathology, *Rumah Sakit Pugeran, Jogjakarta, Bulaksumur, Indonesia* (02483)

From the data available it is clear that trophoblastic neoplasms are frequent in Asia, including Indonesia, and in other tropical countries. Factors resulting from the different conditions of life in various parts of the world, such as race, nutrition, socio-economic status, hygiene, number of pregnancies and abortion may be responsible. In order to study these factors it is proposed to analyze the data from Yogyakarta, Indonesia, which has a high frequency of trophoblastic neoplasia. This study will focus on the epidemiological aspects of choriocarcinoma and hydatidiform mole with special reference to incidence, geographical distribution and etiological factors. Data on pathologically confirmed cases of choriocarcinoma during 1973-1981 and of hydatidiform mole from 1976 through 1981 will be collected, using data from hospital based cancer registration.

EPIDEMIOLOGICAL STUDY ON LUNG CANCER

S. Tokudome, Saga Medical School, Dept. of Community Health Science, *Nabeshima, Saga 84001, Japan* (02293)

A case-control study on lung cancer is proposed in Fukuoka city in order to evaluate mainly familial factors along with other etiological factors such as smoking, occupation, air-pollution, and previous diseases. Five hundred hospitalized lung cancer cases are being asked to complete a uniform questionnaire. Controls, matched for age, sex, and residence are selected from the general population, and are asked to complete the questionnaire mailed to them. Concurrently, family composition and vital status are verified by Koseki - the Japanese population registration system.

GASTRIC CANCER AND ENVIRONMENTAL MUTAGENS

P. Tosi, Universita degli Studi di Siena, Inst. of Pathology, *8, Via Laterino, 53100 Siena, Italy* (02294)

The objective is to delineate environmental factors in the etiology of gastric cancer. Living gastric cancer patients will be identified (survey of hospital records relating to gastroscopy and gastric surgery) and age- and sex-matched patients who have had cystoscopy and hernia or gallbladder surgery will be used as controls. Patients and controls will be interviewed on: (1) preparation and ingestion of foodstuffs and history of tobacco and alcohol use, (2) occupational exposure, (3) place of residence in Siena province and years outside this area, (4) genetic data and location of all first degree relatives. 24 hour urine specimens for mutagenicity studies, and drinking water specimens for nitrite and nitrate content studies will be collected. The mutagenicity data on Salmonella histidine revertants will be compared between the following groups: (a) living patients and age- and sex-matched controls and spouses before and after cessation from smoking, (b) first degree relatives of living and deceased patients and controls and spouses of each. Relatives living in the same household as patients will be analyzed separately from those living outside these households. The data will be compared with those obtained in similar on-going studies of San Marinese in San Marino and in the Detroit area of the U.S.

RESEARCH PROJECT 'THOROTRAST' - INVESTIGATIONS TO EVALUATE THE LONG TERM EFFECTS CAUSED BY ARTIFICIAL RADIATION IN MAN

G. Van Kaick, Deutsches Krebsforschungszentrum, Inst. fur Nuklearmedizin, *Im Neuenheimer Feld 280, D6900 Heidelberg, Federal Republic of Germany* (02529)

Thorotrast, a 25% colloidal solution of Thoriumdioxide was used as a contrast medium between 1930-1950. After intravenous injection the ThO2-particles were stored in the reticuloendothelial system (RES). The project aims at discovering the late effects of chronic radiation exposure by studying a large number of patients injected with Thorotrast, comparing these results with a corresponding control group and examining the relationship between late effects and radiation dose. The study includes: biophysical investigations to calculate the total effective radiation dose; clinical, biochemical and radiological examinations to determine the state of health; classification of the causes of death for patients who died; statistical analysis of the results obtained. To date the names of 5159 Thorotrast patients and 5160 control patients have been obtained from records in different hospitals of West Germany: 901 Thorotrast patients and 669 control patients have been examined clinically. Living patients were reexamined every two years. Apart from this epidemiological study the following investigations are being carried out: animal experiments to (1) investigate the distribution of Thoriumdioxide particles within the body and calculate the resulting tissue doses and (2) to estimate the non-radiation effects of deposited Thoriumdioxide.

JAPAN-HAWAII CANCER STUDY

A.M. Nomura, Kuakini Medical Center, Dept. of Pathology, *347 N. Kuakini St., Honolulu, Hawaii* 96817

In recent years the Japanese in Hawaii have experienced cancer incidence and mortality rates which are intermediate to the rates of indigenous Japanese and US-Whites. Because genetic variables are presumably held constant in comparisons between native and migrated Japanese, this shift in the cancer experience of the 'Westernized' Japanese in Hawaii strongly suggests that environmental factors play a major role in oncogenesis. Furthermore, this spontaneous sociomedical experience among the Japanese provides a unique opportunity to isolate specific environmental, biochemical and pathologic variables which may be etiologically associated with different types of cancerous lesions. Of special interest is the observed reciprocal relationship of gastric and colorectal cancer among the migrant Hawaii Japanese. They have manifested a falling rate for gastric cancer and a rising trend for malignant colorectal tumors. The study has utilized the examined population of the Honolulu Heart Program, which consisted of 8,006 men of Japanese ancestry who were born from 1900 through 1919 and seen from 1965 to 1968 in Hawaii. Approximately 6,800 of the men have since returned for a repeat examination, and these are the men now under surveillance in the Japan-Hawaii center study. There are three major end points in this surveillance: (1) The occurrence of new cases of cancer; (2) deaths due to different types of cancer; (3) appropriate pathologic findings from surgical specimens or necropsies.

EPIDEMIOLOGICAL ANALYSIS OF EFFECTS OF RADIUM

R.E. Rowland, Argonne National Lab., Radiological & Environmental Research Division, *9700 S. Cass Ave., Argonne, Illinois* 60439

Epidemiological studies are being conducted in order to determine the health effects of exposure to radium. Persons exposed to radium in various parts of the United States are being traced from records of radium dial companies and from other sources. Follow-up of persons located includes determination of vital status and analysis of causes of death (obtained from death certificates) for all, and medical examination, measurements of body radioactivity, and analysis of autopsy reports or materials for part of the group. Analyses of morbidity and mortality are made within the group in relation to body burden of radium. Dose-response patterns are being determined for bone sarcomas with reference to bone sarcomas and carcinomas of the mastoids and the paranasal sinuses. Further analyses will involve other diseases. Mortality and morbidity in specific subgroups of radium cases (e.g., radium dial workers ascertained from employment lists) are being compared with U.S. statistics, with consideration of sex, and other demographic characteristics. At present, about 2,000 persons have been located and measured for radioactivity. Studies of the health of the offspring of certain groups (i.e., female radium dial workers) are also planned.

IMMUNODEFICIENCY-CANCER REGISTRY

J.H. Kersey, University of Minnesota, Minneapolis Campus, School of Medicine, Dept. of Laboratory Medicine & Pathology, *1305 Mayo, Minneapolis, Minnesota* 55455 (D-IARC-79-885)

The Immunodeficiency-Cancer Registry is a non-population based registry which attempts to collect all case reports of cancer in individuals who have a prior history of naturally occurring immunodeficiency disease. There are approximately 16 defined entities which are included in the Immunodeficiency-Cancer Registry having been accepted by the World Health Organization Committee on Primary Immunodeficiencies. Efforts are underway, however, to develop a population-base for the registry. One survey of U.S. medical institutions was performed during a 9-month period, November, 1975-July, 1976 to elicit responses from immunologists and paediatricians about the incidence of these 16 diseases; preliminary results indicate that the methodology, when improved, should yield a reliable indicator of the frequency of immunodeficiency diseases in the general population, and thus produce better statistics on the cancer risk for immunodeficient patients. For each case of immunodeficiency disease and cancer registered in the registry, we request (1) clinical history demonstrating immunodeficiency, (2) laboratory tests of immune function, (3) surgical pathology reports and autopsy reports and tumor specimens for independent pathological review.

SEARCH FOR AN ETIOLOGICAL AGENT IN HODGKIN'S DISEASE AND RELATED LYMPHO-PROLIFERATIVE DISEASES

B.E. Henderson, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033

There have been several recent reports of familial and non-familial clustering of Hodgkin's disease. The unusual aggregations suggest the possibility that Hodgkin's disease is caused by an environmental agent, possibly a horizontally transmitted virus. Results of HL-A typing indicate that out of a total population, only a subset is susceptible to development of Hodgkin's disease upon exposure to this hypothetical environmental agent. Some of these more susceptible individuals may possibly be found among the members of families with multiple cases of malignant lymphoproliferative diseases. The University of Southern California, school of Medicine, Cancer Research Program is currently involved in trying to identify these most susceptible individuals. In order to follow up the earlier studies of Hodgkin's disease as well as to obtain new information on the other malignant lymphomas, a broad study has been initiated of all malignant lymphoproliferative neoplasms diagnosed during 1972 and 1973 in Los Angeles county. The approximately 2,400 (ALL 180, CLL 24, multiple myeloma 360, Hodgkin's disease 440 and non Hodgkin's lymphomas 1,180) neoplasms expected during this two-year period are being studied in detail. The basis for the histological diagnosis will be reviewed by Dr. Lukes and his co-workers and, as a minimum, the pathological slides on all Hodgkin's and non-Hodgkin's lymphomas during 1972 will be reviewed.

NATIONAL HUMAN MONITORING PROGRAM FOR PESTICIDES

F.W. Kutz, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

The National Human Monitoring Program for Pesticides is responsible for determining incidences, levels, and other evidence of pesticide exposure in the general population of the conterminous United States, and for identifying changes and trends. This programme currently comprises two major projects. The older of these consists of the collection and organochlorine pesticide residue analysis of adipose tissue samples collected from residents of cities selected according to a proportionate stratified-random design. For each of these 40 areas an annual quota reflecting age, sex, and race distribution at the most recent national census is defined. Approximately 1,600 human fat specimens are scheduled for collection annually. In addition to the individual results of the multi-residue analysis, data collected for each person sampled include: age, race, sex, geographic location, occupation, height, weight, and diagnoses at the time of sampling. All data are managed electronically, making retrievals of any of the above possible. More recently, in cooperation with the Public Health Service's Health and Nutrition Examination Survey II (HANES II), blood serum and urine are being collected from a sub-sample of 7,500 persons in the general population of 75 cities over a 3-year period to yield baseline data on levels of selected organochlorine insecticides in serum. Urine analysis will provide information on organophosphate and phenoxy herbicides, and other new classes of pesticides. A wide range of epidemiological studies is planned.

HEALTH EFFECTS OF ASBESTOS EXPOSURE IN NAVAL SHIPYARD WORKERS

L.N. Kolonel, University of Hawaii System, Manoa Campus, Cancer Center of Hawaii, Epidemiology Program, *1997 East West Rd., Honolulu, Hawaii* 96822

A retrospective cohort of 9,000 male shipyard workers employed at the Pearl Harbor Naval Shipyard in 1950, and subsequently through 1968, has been identified. Complete work histories have been obtained for each man, as well as records of environmental levels of asbestos. Follow-up of these men for their vital status as of 1974 is in progress. Mortality from all causes, respiratory diseases, and site-specific cancer will be compared with that expected based on the mortality experience of the Hawaii population of comparable age, sex and race. Smoking histories will be obtained from the living cohort in Hawaii, who will then be followed prospectively for morbidity and mortality over the next several years. The possible synergism between smoking and asbestos exposure in the risk of cancer will also be examined.

3.2150,

NEOPLASIA-PREDISPOSING GENES IN MAN

M. Swift, University of North Carolina, Chapel Hill Campus, Child Development & Mental Retardation Research Inst., *Chapel Hill, North Carolina* 27514 (D-IARC-79-973)

A method has been developed which identifies a class of genes relatively important in neoplasia-predisposition in the general population and which measures the risk of malignant neoplasms for heterozygous carriers of each gene in this class. This method is based on autosomal recessive syndromes associated with cancer and leukemia. The heterozygous carriers of genes for each of these syndromes occur in the population at a frequency between 0.01 and 0.001, so that detecting a significant increase in risk of malignant neoplasm for the heterozygous carrier of any of these genes would imply that that gene is an important neoplasia-predisposing gene of man. An association between malignant neoplasms and each gene in this class can be detected by a retrospective study of the illnesses and causes of death in families with homozygous probands (affected with a particular autosomal recessive syndrome), since heterozygotes are frequent in such families. It is possible to measure the general risk of malignancy associated with each gene studied and to detect associations between specific types of malignant neoplasms and individual genes. These associations may provide useful leads for investigating the genetic basis of tumor induction in man by specific oncogenic agents.

LONG-TERM MORTALITY OF STEELWORKERS

C.K. Redmond, University of Pittsburgh, Graduate School of Public Health, Dept. of Biostatistics, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260

The objective of this study is the identification of work areas, occupations, and processes within the steel industry that are associated with unusual mortality from specific diseases indicative of health hazards in the work environment. Two cohorts of steelworkers consisting of (1) all male workers employed at seven US steel plants in 1953 and (2) all oven workers employed at twelve coke plants, plus controls, in the USA and Canada in 1961 have been followed for mortality through 1970. Mortality rates for specific causes of death among men employed in various jobs and work areas are compared with rates from the total steelworker population. Reports have been prepared on coke oven workers, crane operators, and open hearth workers, sheet and tin mill workers, and masons. Methodological studies have been prepared that discuss proportionate mortality versus mortality rates, effects of using different kinds of control groups, and retiree mortality patterns as they compare to the total population-at-risk. The updating of vital status of all workers through 1975 was recently completed, along with the corresponding updating of mortality by work area, and the re-evaluation of cause-specific mortality patterns among coke oven workers. Other work areas in which excess cancer mortality was observed were the foundry (genito-urinary cancers), electric furnace (urinary cancers), sheet and tin mill (lymphatic and haemotopoietic cancers), and blacksmith shop (respiratory cancers).

MORTALITY EXPERIENCE OF PRINTING PRESSMEN IN THE UNITED STATES AND CANADA

E.C. Hammond, American Cancer Society Inc., Dept. of Epidemiology & Statistics, *777 3rd Ave., New York, New York* 10017

With the assistance of the Printing Pressmen's Union, a cohort of all members of this union in 1960 has been established (this particular cohort contains some 65,000 individuals). The mortality experience of the individuals concerned is being examined. As in other studies, expected deaths will be age, year and sex specific. In a second study, a cohort has been established of all members of the union local in New York City which includes all printing pressmen employed by newspapers and similar shops ('web pressmen') in 1954. Although this cohort contains fewer than 2,000 individuals, it will be possible to undertake virtually complete tracing of all its members and to undertake detailed consideration of appropriate hospital and pathological data. Again, expected deaths will be compared with those observed, by cause. A preliminary analysis has been completed.

THE RELATIONSHIP OF UVB (ULTRAVIOLET) RADIATION TO CANCER OF THE SKIN IN MAN

F. Urbach, Temple University, School of Medicine, Dept. of Dermatology, *3322 Broad St., Philadelphia, Pennsylvania* 19122

There is strong circumstantial evidence that skin cancer in man is causally related to chronic exposure to solar ultraviolet radiation. series of automatic, integrating UVB meters has been designed, built and installed in various locations. These meters measure sunburn-effective UVB continuously. Measurements of UVB are being compared to either incidence or prevalence of skin cancer in selected areas sufficiently differing in insolation in order to determine the relationship of UVB, stratospheric ozone concentrations and physical sunlight exposure to the induction of skin cancer in man.

STATISTICAL METHODS IN CANCER EPIDEMIOLOGY

N. Mantel, George Washington University, Biostatistic Center, Dept. of Statistics, *7979 Old Georgetown Rd., Bethesda, Maryland* 20014

The spontaneous occurrence of cancer in humans, or induced occurrence in laboratory animals, reflects the interplay of many variables. Also multivariate in nature are the factors influencing survival times or remission times of individuals with cancer, whether treated or left untreated. The multivariate statistical problems which arise may relate to identifying individually important variables which may be causative, making prognosis of survival or other predictions for cancer patients with a specified multivariate vector, and seeking to identify optimal therapeutic procedures for such patients. Data available for such analyses may be prospective or retrospective in nature, and for the prospective case will generally involve incomplete observations. Recent developments in mathematical models and statistical approaches for relating response to multivariate regressors, specifically models involving hazard functions and generalized logistic regression, open the way to handling such problems, and it is the effective use of such models and approaches that I plan to study. In some instances these approaches may bear modification as, say, using a classification approach when data are abundant but variables to be studied few in number. I anticipate that tie-ins with other problems of cancer epidemiology will develop. Related, or variant methods, may be appropriate in the study of potential environmental carcinogens. Methods for safety evaluation of such agents represent a preventive epidemiology approach.

CANCER OF THE PANCREAS

B. MacMahon, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115

The study is designed to evaluate quantitatively the environmental factors suspected to be associated with the aetiology of cancer of the pancreas, and to investigate other possible risk factors. For each case, two controls are selected at the same hospital. Both index cases and controls are interviewed on demographic variables, past medical history and social and occupational history. The population will consist of approximately 500 cases and 1000 controls.

RESPIRATORY EFFECTS OF CHLOROMETHYL ETHERS

W. Weiss, Hahnemann Medical College & Hospital, Medical College, Dept. of Medicine, *235 N. 15th St., Philadelphia, Pennsylvania* 19102

A prospective study of 125 male workers at a chemical plant by periodic chest x-rays and questionnaires was conducted from 1963 to 1968. In 1965 a spirogram was done in 103 men. Additional follow-up has been continued to the present. Ninety-one men had been exposed to the chloromethyl methyl ether containing bis (chloromethyl) ether as a contaminant. Each man was assigned an exposure index obtained by multiplying a semiquantitative time-weighted average exposure rating against the years of exposure. The men were divided into an unexposed and three exposed groups according to the magnitude of the index. The groups were similar except that the most heavily exposed group had more non-smokers and more light current cigarette smokers than the other groups. There was a dose-response relationship between chemical exposure and the prevalence of chronic cough and expectoration, and the 10 year incidence of bronchogenic carcinoma with no cases among lightly exposed men and increasing risk in moderately and heavily exposed men. Although the groups did not differ with respect to the frequency of abnormal forced vital capacity and forced expiratory volume in one second, there was a rough relationship between the degree of chemical exposure and the frequency of low end-expiratory flow rate on the spirogram. There was an inverse relationship between smoking habits and the risk of lung cancer. All of the cancers were small cell in type. Observation of the cohort is continuing.

EPIDEMIOLOGY OF HISTOLOGICAL TYPES OF LUNG CANCER

W.E. Morton, Oregon State Higher Education System, University of Oregon Health Sciences Center, School of Medicine, Dept. of Public Health & Preventive Medicine, *3181 S.W. Sam Jackson Park Rd., Portland, Oregon* 97201

The continued annual increases in lung cancer mortality seem excessive in view of the static smoking behavior during the past decade, suggesting that other environmental influences need more study. A pilot study of incidence during 1968-1972 among residents of three counties in the Portland metropolitan area identified 2,002 cases. Most were smokers (97% in males, 80% in females); a minority had a family history of cancer (males 32%, females 42%). The different histological types had major differences in their socio-economic, geographical, and occupational risk patterns, suggesting that perhaps they should be regarded as distinct diseases. Major sex differences in socio-economic patterns of risk suggested the importance of occupational confounding among men. Occupational risk differences among both sexes far exceeded those noted with other risk factors, suggesting that occupational factors deserve primary emphasis in future efforts toward lung cancer control. Several occupations had high risks for three or more histological types, but much more common was the situation in which only a single histological type was excessively frequent in the presence of an unremarkabale rate for total lung cancer. Thus the identification of occupational hazards for lung cancer will become significantly more

sensitive if histology-specific rates are used rather than total rates. The study is currently being extended to include the years 1963-1977. In those occupations and industries where excessive lung cancer risks are confirmed, it is hoped to initiate hazard identification studies.

STUDY OF ANIMAL CONTACTS IN LEUKEMIA
I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201 (00008)
Recent evidence has suggested that there may be significant relationships between leukemia occurring in household pets and that occurring in humans. The present analysis, conducted in collaboration with Dr. Hipolito Pabon of Colombia, is based upon the Tri-State Leukemia Survey of a decade ago. Detailed animal contact histories of large number of leukemic children as well as controls were taken. The results are being analyzed in terms of the numbers and types of animal contacts among the leukemic children and controls during their life-times as well as during the relevant pregnancies of the mothers. Analysis continues.

ETIOLOGY OF HUMAN CANCER
F.P. Li, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Clinical Epidemiology Branch, *35 Binney St., Boston, Massachusetts* 02115
The objective is to study the epidemiology of human neoplasms and to develop etiologic hypotheses through close bedside observation of individual patients. Adult and pediatric cancer patients are interviewed for clues to the etiology of their cancer. Clues identified through the interviews are pursued in clinical and epidemiological studies. In addition, laboratory studies have been carried out in several families with strong histories of cancer to identify possible inherited defects or environmental risk factors.

EPIDEMIOLOGY OF CANCER IN A LARGE NON-SMOKING POPULATION
J.L. Lyon, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Family & Community Medicine, *1400 E. 2nd S., Salt Lake City, Utah* 84112
Approximately 73% of the population residing in the state of Utah are members of the Church of Jesus Christ of Latter-Day Saints (LDS -commonly called Mormons). This church proscribes the use of alcohol, coffee, tea, and tobacco. Using a population-based cancer registry with data from 1966 onward, cancer incidence is estimated to be 20% less in the LDS than the non-LDS within the state. Major contributions to this decrease are made by cigarette-associated sites. However, unexplained differences in the area of uterine cervical cancer, stomach and colon cancer exist. Decreases in cancer unrelated to religion are also noted, such as pancreas. Currently, analysis of registry records is being carried out to better characterize the differences by socioeconomic class, urban-rural differences, etc. In the near future, case-control studies to better identify specific etiologic agents will be mounted in ovarian cancer, cervical cancer, pancreatic cancer, colorectal cancer. A paper on cancer (melanoma and prostate) in relation to religion will be published in 1980.

STUDIES ON THE PRESENCE OF ANTIBODIES TO MOUSE MAMMARY TUMOR VIRUS IN PATIENTS WITH BREAST CANCER AND SUITABLE CONTROLS
L.L. Dmochowski, University of Texas, University of Texas System Cancer Center, M.D. Anderson Hospital & Tumor Inst., Dept. of Molecular Carcinogenesis & Virology, *6723 Bertner Ave., c/o Texas Medical Ctr., Houston, Texas* 77030
OBJECTIVE: Search for antibodies to mouse mammary tumor cells and mouse mammary tumor virus in sera of breast cancer patients by using techniques such as fixed and membrane immunofluorescence tests and horseradish peroxidase test as seen by light microscopy. Furthermore, use of immunoelectron-microscopy techniques such as horseradish peroxidase and immunoferritin labeling. The search is comprised of sera from patients of various ages and of different nationalities and races and suitable controls. Sera from patients during various stages of disease and treatment are being investigated. Relationship of antiviral antibodies to suppression of in vitro lymphocyte stimulation is being studied.

EPIDEMIOLOGIC SURVEY ON HAWAII RESIDENTS
L.N. Kolonel, University of Hawaii System, Manoa Campus, Cancer Center of Hawaii, Epidemiology Program, *1997 East West Rd., Honolulu, Hawaii* 96822
In 1975, a brief epidemiological questionnaire was added to the on-going Health Survey of Hawaii, a representative, statewide survey patterned after the US National Health Survey. About 6,000 households are surveyed annually, and the epidemiological questionnaire will be administered for a period of 5 years. This questionnaire seeks information on smoking, drinking and dietary habits, which can be related to various demographic data (age, sex, race, place of residence, education, income, etc.), which are collected routinely in the survey. Data from the first year of the epidemiological survey are now being analyzed in relation to some of the interesting differences observed in cancer incidence and mortality among the various ethnic groups in Hawaii. The cohort developed through this survey will be followed prospectively for cancer risks in relation to antecedent dietary and smoking habits.

EPIDEMIOLOGY OF HEPATIC ANGIOSARCOMA
H. Falk, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Bureau of Epidemiology, Cancer & Birth Defects Division, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333
This project started about four years ago with the discovery of the association between hepatic angiosarcomas and long-term exposure of industrial workers to vinyl chloride. Subsequently, a survey of pathologists in the USA was conducted and to date about 250 cases of human hepatic angiosarcoma have been identified and the slides reviewed. As noted, some of these cases were caused by vinyl chloride. Other cases were caused by or associated with exposure to Thorotrast or to arsenical compounds. The majority of the cases have no known environmental or industrial aetiology. The epidemiological study which is continuing involves obtaining detailed work and exposure histories from all these patients or from their living relatives. The pathological aspects of the study are conducted by Drs. Thomas, Popper and Teller. The epidemiological aspects are under Dr. Falk and other epidemiologists at the Center for Disease Control in Atlanta, Georgia.

MORTALITY EXPERIENCE OF CERAMIC TILE SETTERS IN THE NEW YORK CONSTRUCTION INDUSTRY
I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *1 Gustave L. Levy Pl., New York, New York* 10029
We have been interested in obtaining information concerning the mortality experience of individuals working in the construction industry in New York, potentially indirectly exposed to asbestos dusts within that industry, but not directly so exposed by virtue of the nature of their own work. One such group has been the ceramic tile setters, a 'finishing trade', working in the same buildings as trades using asbestos materials in other work, but whose own materials do not contain asbestos. We have established a cohort of all ceramic tile setters in the New York construction industry in 1955 who were members of their union for at least five years. This was done with the cooperation of the Tile Setters' Union. The mortality experience of this cohort is being investigated through 1973. A sample of 100 tile setters was also clinically examined.

EPIDEMIOLOGY OF CANCER OF THE CERVIX IN HIGH RISK POPULATIONS

S. Graham, State University of New York, Buffalo Campus, School of Social Science & Admin., Dept. of Sociology/Social & Preventive Medicine, *3435 Main St., Buffalo, New York* 14214

This study examines factors that have been found to be associated with cancer of the cervix: large number of sexual partners; contraceptive types which expose women directly to their partners; early age at first intercourse, marriage, and pregnancy, number of pregnancies and use of the vaginal douche. These factors are being examined in women known to be at higher than usual risk of cancer of the cervix: Blacks and, because of their low socio-economic status, Chicanos. In addition, a number of investigators have inquired into the presence of microorganisms or antibodies to them in patients with cancer of the cervix and in controls. Almost always, cases reveal much larger percentages possessing antibodies to herpes type 2 virus. The aim is to examine whether cases can be distinguished from controls on the presence of Herpes in instances where there has been only one sexual partner as well as in instances where there have been many. It would also be of interest to know whether among cases with only one and those with many partners the proportion of women with antibodies is the same, and higher than among controls with one or many partners. If these conditions were obtained, it would suggest that herpes type 2 virus is strongly implicated. The sources of lower social class Chicano and black women with cancer of the cervix and appropriate controls were the Los Angeles County-University of Southern California Hospital, the Martin Luther King Jr. Hospital in Los Angeles, Harbor General, and California Hospital. Controls consist of women patients at the same hospitals, matched on age, with non-neoplastic, non-pelvic diseases. Each case and control will have 15 ml of blood drawn. Antibody titre to herpes virus types I and II was quantitated using a modification of release of 51 chromium. Data collection was completed in July 1979. 255 Chicana and 121 black cases have been interviewed. In addition, data on 151 black and 194 Chicana controls were gathered.

MORTALITY EXPERIENCE OF WORKERS IN THE PAINTING TRADES IN THE U.S. AND CANADA

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *1 Gustave L. Levy Pl., New York, New York* 10029

Workers in the painting trades have a variety of exposures to known or suspected carcinogenic agents, ranging from asbestos dusts to benzene and other solvents. Vinyl chloride exposure has also been identified in some circumstances. With the cooperation of the Painters' Union in the United States and Canada, we are establishing a cohort of all registered members of the union in 1965. These individuals will be followed prospectively from that point onwards and their mortality experience analyzed. It will probably be possible to categorize the full cohort by trade (general painters, dry wall construction workers, sandblasters, iron painters, paper hangers, wood finishers, paint makers, etc.) and the mortality experience of the various groups will be separately considered. Another cohort of all members of the Painters' Union in New York City in 1960, who had maintained membership for at least five years, is also available and will be studied prospectively from that point to the present. In order to obtain background information concerning types of lesions which may be of particular interest, 1,000 members of the union have already been examined clinically, with appropriate laboratory studies, and another 2,500 men will be studied during the two coming years. In addition, industrial hygiene studies of the environment in the painting trades are being undertaken.

LONG-TERM PROSPECTIVE OBSERVATION OF ASBESTOS INSULATION WORKERS IN THE NEW YORK METROPOLITAN AREA

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *1 Gustave L. Levy Pl., New York, New York* 10029

On January 1, 1943, there were 632 members of the Asbestos Insulation Workers' Union in the New York metropolitan area. The entire cohort has been followed prospectively since. All those alive January 1, 1963, were clinically investigated and, among other things, cigarette smoking habits were recorded. Mortality experience of the cohort is being analyzed. By January 1, 1963, 262 individuals had died and approximately 250 more deaths had been recorded by the end of 1976. In addition, 890 workers joined this union between January 1, 1943, and December 30, 1962, and their experience is also being studied epidemiologically and clinically. Their mortality experience will reflect risk past World War II.

EPIDEMIOLOGICAL STUDIES OF URANIUM MINERS AND MILL WORKERS

V.E. Archer, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Health Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Uranium miners have been found to have an excess of lung cancer and mill workers to have an excess of lymphomas. A much larger group of mill workers is now being studied by a retrospective cohort study to determine the magnitude of the lymphoma excess. Identification of the substance responsible is being attempted. Two groups of uranium miners are being studied, one of about 4,300, and a much larger one of about 15,000. These groups are being used to determine exposure-response curves, and the different factors which influence the shape of those

curves; effects of exposure on the sex-ratio of offspring, the effect of age at first exposure on incidence and latent period, and the dose rate effect.

STUDY OF THE INCIDENCE AND NATURAL HISTORY OF GENITAL TRACT ANOMALIES AND CANCER IN OFFSPRING EXPOSED IN UTERO TO SYNTHETIC ESTROGENS

R.H. Kaufman, Baylor College of Medicine, School of Medicine, Dept. of Oostetrics & Gynecology, *1200 Moursund Ave., Houston, Texas* 77025
Synthetic estrogenic substances (DES) have been administered to pregnant women for approximately three decades, primarily with the intent of preventing spontaneous abortions. From 250,000 to 1,000,000 females and an equal number of males were exposed to DES during gestation. Recently, studies have been reported linking such exposure to DES with development of specific malignancies and other abnormalities of the female lower reproductive tract. Whether significant abnormalities of the genitourinary system also occur among males is not known. The aims of this project are to follow the course of development of persons exposed to DES in utero (and comparison groups of unexposed persons) in order to detect the occurrence of and secure treatment for possible anomalies or malignancies which may arise. Over a period of five years of follow-up, for subgroups at various ages when entering the project, the experience of groups remaining free of all pathology, developing new pathology, continuing with pathology similar to that at entry, or treated in accordance with one or more special protocols, will be analyzed. The risk of these outcomes will be determined among cohorts where DES exposure status is known, and treatment protocols may be devised and implemented for particular outcomes which are observed.

DESAD PROJECT - INCIDENCE AND NATURAL HISTORY OF GENITAL TRACT ANOMALIES IN WOMEN EXPOSED IN UTERO TO NON-STEROIDAL ESTROGENS

L.T. Kurland, Mayo Clinic, Dept. of Medical Statistics & Epidemiology, *200 1st St. S.W., Rochester, Minnesota* 55901
This study is intended to assess, comprehensively, the magnitude and severity of the health hazards to exposed daughters which may result from the administration of exogenous, non-steroidal estrogens (DES) to pregnant women over the past three decades in the United States. Beginning with available medical records in selected areas of the country, exposed and unexposed offspring have been identified, contacted, and entered into the study in a manner designed to eliminate selection bias. For subjects presenting themselves independently or by referral from physicians, verification of exposure must have been obtained before entry. These self-selected groups are examined and followed in the same manner as those identified by review of records. At entry into the study, all participants receive a standard gynecological and colposcopic examination, provide cervical and vaginal cytology specimens, have biopsies taken when indicated by colposcopy, and complete a general female health history interview. Information regarding the participant's mother is also obtained. At yearly (or closer) intervals, each participant is to return for examinations similar to those at entry and provide updated health information. To date, over 1,500 exposed and 750 unexposed women indentified through the review of prenatal records have entered the study. Over 1,800 women in the walk-in and referral categories have entered. Many participants have now been followed four to five years. Publications have been completed concerning the baseline pathological, cytological, colposcopic, gynecological, and obstetrical findings. Evaluation of the changes over time of these findings, recommendations as to health care and/or treatment, and planning for the long-term follow-up of this cohort remain as the important tasks of this study.

PROSPECTIVE STUDY OF THE RELATIONSHIP OF HORMONAL AND SOCIOLOGICAL FACTORS TO THE DEVELOPMENT OF CANCERS OF VARIOUS SITES

A.M. Lilienfeld, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205
The objective is to see if serological changes found in cancer patients antedate the development of their disease by comparing serum specimens from patients and controls taken at the same time and before cancer had developed in the patients. Serum was collected in 1974 from nearly 26,000 volunteers in Washington County, Maryland, and stored at minus 100 degree F. In addition to identification data, information was collected on marital status, education, smoking, date of last menstrual period (for women), and medications, with special emphasis on hormonal preparations. A cancer registry has been maintained in the county since 1958. When sufficient numbers of cases have developed since 1974, serum of cases and matched controls will be withdrawn from storage to be examined for hormone, antibody, protein, or trace metal levels, as indicated by previous concurrent case-control studies.

A PROSPECTIVE STUDY OF CANCER RISK IN TUBERCULOSIS

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201 (D-IARC-79-831)
Interest in the long-hypothesized association between tuberculosis and cancer has been intensified by laboratory studies demonstrating that tubercle bacilli (i.e. BCG) potentiate host immune responses to challenge. Recent experiments in man suggest that BCG not only evokes non-specific cell-mediated immunity but also increases host resistance to specific tumors such as melanoma, sarcoma and breast cancer. In view of these findings, a type of natural experiment in cancer prevention is underway. A large cohort of tuberculosis patients is followed prospectively through time to death or survival as of December 31, 1974. The outcome variables of interest are cancer mortality and morbidity. Observed cancer risk will be compared with that of the contemporaneous general population similar in age, sex and race. The prospective design of the study will make it possible to study the association (if any) between tuberculosis and all types of cancer: Those in which it is significantly positive, those in which it is significantly negative and those in which there is no significant relationship at all. Retrospective studies do not have this capacity. Should a significant relationship between antecedent tuberculosis and cancer be demonstrated in this population and confirmed by additional studies, the findings could ultimately lead to mass BCG or tuberculin vaccination among the young as a cancer preventative.

IDENTIFICATION OF HIGH-RISK OCCUPATIONAL GROUPS

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201
Evidence from the laboratory as well as from clinical observations and epidemiological studies is substantiating earlier findings on the role of occupational factors in human carcinogenesis. Recent clinical and epidemiological evidence relating environmental exposure to such materials as asbestos, vinyl chloride, radiation, etc. strongly suggests that a major effort should be undertaken to identify occupational agents which may be responsible for human cancer, parkinsonism and other chronic disease. An etiologically meaningful analysis of occupational histories must have at least two characteristics: first, the analysis must be conducted in such a fashion as to permit comparisons with the findings of previous investigators; and second, the analysis must make identification of potentially dangerous occupational exposures possible. To accomplish these dual purposes, two completely independent analyses of occupational data are being undertaken, the first in accordance with the United States Census Bureau Index of Industries and Occupations, making it possible to compare results with those of previous investigators who have used the same index, and the second classifying all occupational exposures judgmentally, for the purpose of identifying all possible potentially hazardous occupational or industrial categories. After identifying specific occupational hazards in this fashion, previous investigators could be contacted with a view to reanalyzing their data in terms of the potentially dangerous occupations or industries newly identified.

STUDY OF LYMPHOID TISSUES IN NEOPLASIA

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201
This study is designed to measure the risk of subsequent development of cancer in persons who have undergone surgical removal of the vermiform appendix and/or palatine tonsil and to compare this risk with that in a control population. There has been a recent increase of interest in the lymphatic system and its relationships to normal and abnormal growth processes. To this end, an attempt is being made to trace a cohort of approximately 5,000 persons who were appendectomied and another cohort of approximately 4,000 persons who had their tonsils removed at the Johns Hopkins Hospital from 1925 to 1936. When traced, the mortality and, perhaps, incidence of cancer among them will be compared to that of a matched control group who underwent other types of surgery at Johns Hopkins during the same period of time. Both the appendectomy and tonsillectomy cohorts have been identified and follow-up as to survival and cause-specific mortality is now underway.

AN INVESTIGATION OF THE MALE ROLE IN CERVICAL CANCER

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201
Studies utilizing a number of different approaches suggest that the male sex partner may play a role in the aetiology of cervical cancer. Demographic analyses reveal higher cervical cancer mortality rates among married and previously married women than among single women or virgins. A possible association between penile and cervical cancer has been demonstrated. Considerable evidence has accumulated on the relationship between cervical cancer and the venereally transmitted genital herpes virus, HSV-2. The results of these studies have increased the likelihood of a significant male role in cervical carcinogenesis. The study is designed to provide an additional test of the venereal hypothesis in the pathogenesis of cervical neoplasia. The approach represents an attempt to answer the following question: Is the risk of developing cervical cancer increased among the wives of men who - at sometime in their lives - were married to other women who developed cervical cancer? The study begins with the identification of a large group of women who had cervical cancer in Greater Baltimore during the past 20 years. The husbands of these women are investigated to the extent of identifying all their previous and subsequent wives ('case' wives). A random sample of 'control' wives, similar to the 'case' wives in demographic and marital characteristics is then selected. The cohorts of 'case' and 'control' wives are traced prospectively to death or survival at a recent point in time. The ultimate risk of cervical neoplasia among the two cohorts is compared, utilizing actuarial techniques. This approach affords a direct test of the role of any venereally transmitted male factor in cervical cancer, whether it be viral, chemical or otherwise.

TRI-COUNTY STUDY OF CANCER OF MOUTH, ESOPHAGUS, PHARYNX, LARYNX, STOMACH, COLON, RECTUM, LUNG AND BLADDER

S. Graham, State University of New York, Buffalo Campus, School of Social Science & Admin., Dept. of Sociology/Social & Preventive Medicine, *3435 Main St., Buffalo, New York* 14214

There have been suggestions that diet, alcohol ingestion, oral conditions, and smoking are related to cancer of the mouth, esophagus, and stomach, and that alcohol ingestion and smoking are related to cancer of the larynx. It has also been hypothesized that cruciferous vegetables lower the risk for colon cancer of the lung and bladder. These relationships are the subject of this inquiry. To avoid hospital-related bias and to obtain detailed information on each case, all new cases of cancer at these sites in Erie, Niagra and Monroe Counties in New York State are interviewed. All controls are matched on age (within 5 years) and sex and reside in the neighborhoods of the cases. To obtain all corroborative evidence possible as to dietary habits of subjects, a sample of spouses of cases and controls are also being interviewed. Cases and controls are also asked to complete a 24-hour dietary recall. 1,047 cases comprised of 179 mouth, 108 esophagus, 197 larynx, 37 pharynx, 169 stomach, 270 colon, and 87 rectum cancers have now been interviewed and interviews with lung and bladder cancer cases have begun. In addition, 805 controls, 116 control spouses and 119 case spouses have been interviewed. Data collection will continue as scheduled over the next several years. Multivariate analyses of the results will be carried out for each site as sufficient numbers are obtained. Analysis of 100 case/spouse and 100 control/spouse pairs to determine extent of agreement with regard to the subjects' dietary habits has been completed and a paper is in press.

STUDY OF THE SOCIO-ECONOMIC, ENVIRONMENTAL, AND DEMOGRAPHIC FACTORS THAT MAY INFLUENCE HEALTH STATUS OF UNITED STATES POPULATIONS

D. Gr[illegible]n, Argonne National Lab., Division of Biological & Medical Research, *9700 S. Cass Ave., Argonne, Illinois* 60439

The long range objective is to develop predictive relationships between the socio-economic, demographic and environmental characteristics of regional and local populations and the general health status of these populations. Special attention has been given to the identification of the causes of mortality that may be related to the effluents from existing or proposed major energy systems. A procedure for standardizing mortality measures using county-level socio-economic, environmental, and demographic variables is being developed. The data are derived from 1970 Census Data, 1969-1971 US Vital Statistics, and recent pollution, climate, cigarette and alcohol consumption data. This data base is fully developed for the entire continental United States. Preliminary analyses of subsets of data suggest that about 50% of the variation in various mortality measures can be attributed to socio-economic, environmental, and demographic variables. Current investigations are examining a number of questions including whether the relative contribution of different variables to explained variance in mortality is consistent among geographic regions and whether the influence of pollution on mortality patterns is consistent among populations of differing socio-economic characteristics. The goal of these analyses is an improved understanding of the interplay of factors underlying death and disease risks which in turn will allow more precise predictions of the expected health status of human populations.

3.2192,

CHILDHOOD ENVIRONMENT AND RISK OF HODGKIN'S DISEASE

B. MacMahon, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115

The objectives of this study are (1) to evaluate the hypothesis that risk of Hodgkin's disease is a function of factors in the childhood environment which inhibit infectious transmission; in particular, family size, birth order, and social class; (2) to re-evaluate the association between tonsillectomy and Hodgkin's disease; (3) to evaluate occupational exposures and Hodgkin's disease; (4) to establish a serum bank. This is a two-part population-based case-control study. Part I is conducted in a defined population in eastern Massachusetts. A 4 1/2 year incidence case series has been identified and surviving cases interviewed at home. Age- and sex-matched controls are drawn from the general population and similarly interviewed. Siblings of cases comprise a second control group. Sera are obtained from cases and sibs. Part II is conducted in a defined population in Detroit, Michigan. A similar incidence series has been identified and information is gathered from live cases and sibling controls by mail questionnaire.

RISK OF NEOPLASIA IN NEIGHBORHOOD ASBESTOS DISEASE

E.C. Hammond, American Cancer Society Inc., Dept. of Epidemiology & Statistics, *777 3rd Ave., New York, New York* 10017

It is known that mesothelioma can occur in relatives of asbestos workers. However, it is not known whether or not mesothelioma or lung cancer occurs with greater frequency in persons with low-level exposure, for example, those living near an asbestos plant. We have established cohort of all males over the age of 18 living within a half mile of an asbestos plant in Paterson, New Jersey, 1942-1943; there were approximately 2,500 such individuals. As a control group, we have listed a cohort of men with identical qualifications in another neighborhood of the same city, with similar social strata, but without an asbestos facility. All members of both cohorts are being traced through 1974 and their mortality experience evaluated. We have successfully traced over 95 percent of both groups. In addition, lung tissue of those who have died is being analyzed for its asbestos content, quantitatively, and settled dust in homes at varying distances from the index factory, taken from attic rafters, etc., is being studied for its asbestos fiber burden. In both the epidemiological and environmental investigations, workers employed in the factory and their families are excluded. The first mortality analyses of these data are now completed. Total mortality, total cancer and lung cancer deaths did not differ in the two neighborhoods 20-35 years after first exposure. Follow-up will continue.

EPIDEMIOLOGY OF MALIGNANT MELANOMA

S. Graham, State University of New York, Buffalo Campus, School of Social Science & Admin., Dept. of Sociology, *3435 Main St., Buffalo, New York* 14214

The incidence of malignant melanoma has increased markedly over the past thirty years. The male incidence per 100,000 in Upstate New York has increased from 1.3 in 1941 to 3.4 in 1970. In the same period female incidence rates increased as well. This study aims to examine the effect of sunlight exposure, geography, ethnicity, genetics, hormones, exposure to chemical carcinogens and irradiation on the development of the disease. Cases and controls are being interviewed at Roswell Park Memorial Institute. We plan to continue to interview cases as they occur over a period of five years, until we have approximately 800 cases. Control matched 2 for 1 on age and sex with cases are patients with neoplasms probably unrelated to melanoma, e.g., cancer of the lung and colon. Data collection is on-going. We have interviewed 357 melanoma cases and 375 controls. A preliminary analysis is being planned.

OCCULT CARCINOMA OF THE THYROID GLAND

F.H. Fukunaga, Kuakini Medical Center, Central Laboratory, *347 N. Kuakini St., Honolulu, Hawaii* 96817

A comparative study of occult carcinomas of thyroid glands was done to evaluate relative prevalence in the Japanese living in Hawaii (24%), and in Northern Japan (28%), Canada (5%), Columbia, South America (5.6%) and southern Poland (9%). The Japanese were found to have a much higher prevalence of these lesions although the prevalence of clinical cancer was not increased. The proiect is being continued in the Hawaii-Japanese, and various environmental factors such as diet will be analyzed. Other races in Hawaii are also being studied.

SELENIUM OCCURRENCE AND HUMAN CANCER MORTALITY - FAT AND BEEF CONSUMPTION AND HUMAN CANCER MORTALITY

R.J. Shamberger, Cleveland Clinic Hospital, Dept. of Biochemistry, *9500 Euclid Ave., Cleveland, Ohio* 44106

The aim of this study is to relate selenium occurrence to human cancer mortality. Crude and some age-adjusted mortality show an inverse relationship to selenium bioavailability. Age-adjusted mortality for various cities and states in the United States has been obtained, but less than state-wide data is difficult to obtain. We would like to relate selenium in blood or bioavailability in various countries throughout the world. A major report has appeared in Arch. Env. Hlth 31, 231-235, 1976. The relation between fat and beef consumption to human cancer is also being studied.

CASE-CONTROL STUDY OF USE OF OXIDATIVE HAIR DYES AMONG FEMALE CANCER PATIENTS

K.M. Stavraky, University of Western Ontario, Faculty of Medicine, Dept. of Epidemiology & Preventive Medicine, *1151 Richmond St., London, Ontario, Canada* N6A 3K7

This case-control interview study will attempt to determine whether women with cancers at the sites listed below have a history of more frequent exposure to oxidative hair dyes than women who are of the same age and social class, but who are either healthy or hospitalized for illnesses other than cancer. Cancer patients will be interviewed at both the Princess Margaret Hospital, Toronto, and the Ontario Cancer Foundation Clinic, Victoria Hospital, London. It is proposed to interview about 35 patients with cancer at each site at each center. In Toronto, two controls for each case will be selected at random from the same neighborhood as the cases; in London, two controls for each case will be selected from female patients admitted to the hospital in which the clinic is located. Controls will be matched to the cases for age, within 5 years on either side of the case's age. Results for breast and endometrium have been published and publication of the full study is expected within one year.

HISTORICAL-PROSPECTIVE STUDY OF THE LONG-TERM HEALTH EFFECTS OF EXPOSURE TO FIBROUS GLASS AND MINERAL WOOL

P. Enterline, University of Pittsburgh, Graduate School of Public Health, Dept. of Biostatistics, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260

Objective is to determine the cause-specific mortality experience of workers in the fibrous glass and mineral wool industries for periods up to 50 years after first exposure and relate this to duration and intensity of exposure and to the experience of the general population. Cohorts consisting of male workers with one year or more experience (exposure) in manufacturing between Jan. 4, 1945, and Dec. 31, 1963, will be developed. Vital status of this cohort will be determined as of Dec.31, 1973. Total cohort size is

estimated to be about according to statistical analysis. The risk of death from selected causes will be established with a detailed examination of malignant neoplasms.

NATURAL HISTORY OF CARCINOMA IN SITU OF THE VULVA AND RESPONSE TO VARIOUS FORMS OF THERAPY
E. Friedrich, State University System of Florida, University of Florida, School of Medicine, Dept. of Gynecology & Obstetrics, *1600 Archer Rd., Box J-266, Gainesville, Florida* 32610
Carcinoma in-situ of the vulva is a 'new' disease with a rapidly rising incidence curve. It occurs in young women and does not seem to be associated with invasive carcinoma of the vulva. Some cases have disappeared spontaneously. The present study continues to find, record, and observe cases of carcinoma in-situ of the vulva, to gather data regarding race, age, parity, concomitant venereal disease, concomitant cancer of other location, occupation and - in some cases - response to various modes of therapy.

ASSOCIATION OF LUNG CANCER WITH CIGARETTE SMOKING
G.B. Gori, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Division of Cancer Cause & Prevention, *9000 Rockville Pike, Bethesda, Maryland* 20205
The objective of this retrospective study is to analyze differences in lung cancer incidence rates as a function of cigarette type and smoking habits among case-control groups in Austria, France, Germany, Italy, Scotland, Cuba and U.S.A. Interviews with hospital patients are conducted to obtain data regarding cigarette brands smoked, number of years using each brand, total number of years smoking, patterns of smoking, drinking habits and demographic data. Data for approximately 500 cases and 1,000 controls are collected annually in each participating country. Central data analyses are performed by Enviro Control, Inc., Rockville, Maryland 20852, U.S.A. (Dr. C.J. Lynch).

CHARACTERIZATION OF PROSTATIC CARCINOMA AMONG BLACKS
M.Y. Heshmat, Howard University, School of Medicine, Dept. of Preventive Medicine, *2400 6th St. N.W., Washington, District of Columbia* 20059
The aims of the study are to: 1) Compare the clinical features, plasma hormone (testosterone, oestrone, oestradiol, and prolactin) levels, epidemiological factors, and tumor morphology in high-risk U.S. Blacks, 2) search for factors that may be associated with the development of prostate cancer in the U.S.A., 3) determine in postmortem material the frequency of incidental (non-invasive) carcinoma of the prostate in the two population groups and 4) study the relation between incidental carcinoma and non-neoplastic prostatic diseases and morphological changes in the liver, adrenal glands, breast, testis, and pituitary gland. All new untreated patients with prostate carcinoma are being admitted to the study. Blood samples are drawn from all male patients after admission to the urological services of the collaborating hospitals. All patients with histologically confirmed carcinoma of the prostate and all controls are interviewed about social and demographic factors, family history, food consumption habits, sexual history, past history of illnesses and operations, history of urogenital diseases, and use of contraceptives by sexual partners. Hospital control patients, age-matched, and free of clinically demonstrable neoplastic, urological, and endocrine conditions are used. In addition, the whole prostate gland is collected from consecutive necropsy cases of black men in Washington, D.C. Whole glands with attached seminal vesicles are accessioned, entered into a blind study, weighed, step-sectioned. From patients with the clinical diagnosis of carcinoma undergoing prostatic surgery, the histological grade of the tumor and other morphological features are correlated with clinical staging, hormonal studies, and epidemiological data. As of January 1978, 170 American and 78 African matched pairs (cancer and control) had entered the study.

GENETIC STUDIES OF BREAST CANCER
D.E. Anderson, University of Texas, University of Texas System Cancer Center, M.D. Anderson Hospital & Tumor Inst., Dept. of Medical Genetics, *6723 Bertner Ave., c/o Texas Medical Ctr., Houston, Texas* 77030
The purpose of this study is to identify patients with hereditary types of breast cancer. Patients with family histories of the disease are selected for study; controls are selected from the same patient population but have family histories of neoplasms other than breast. Both groups are studied simultaneously with similar methodological approaches. Family and medical histories are obtained by questionnaires; all reported tumors are verified by a medical, hospital, pathological and/or vital statistics report. Patients are classified according to age at clinical onset, single or multiple primaries, type of family history and associated familial neoplasms. Patients were classified according to family history of breast cancer at time of ascertainment; families in which patients had an affected mother exhibited lifetime probabilities of 30 percent. When affected mothers and patients were further categorized according to age at diagnosis and laterality, families in which both patient and affected mother had premenopausal onset were characterized by a lifetime probability of 40 percent. When one or the other or a close relative had bilateral disease the probability was 34 percent. Unilateral or postmenopausal disease in both was associated with a 20 percent probability. Fifty percent probability was obtained when both had premenopausal disease and one or the other or a close relative had bilateral disease, compared with a probability of 13 percent when the disease in both was unilateral and postmenopausal. A family history of breast cancer in the sister of a patient was associated with lifetime probabilities little different from those expected for women from the general population (7 percent). The only exception was when the patient and her affected sister both had premenopausal disease and one or the other or a close relative had bilateral disease (lifetime probability 50 percent).

EPIDEMIOLOGY OF HEPATOMA AND CHRONIC LIVER DISEASE IN RELATION TO HEPATITIS B INFECTIONS IN TAIWAN
R. Beasley, University of Washington, School of Public Health & Community Medicine, Dept. of Epidemiology, *4000 15th Ave. N.E., Seattle, Washington* 98105
In Taiwan, where alcohol abuse is rare, chronic liver disease accounts for approximately 25% of all deaths of adult males. Approximately half of these deaths are attributed to hepatoma, most with underlying cirrhosis, the other half to cirrhosis without hepatoma. Acute and chronic hepatitis are also very common. There is a high degree of association between these conditions and the hepatitis B surface antigen (HBsAg): hepatoma 90%, cirrhosis 80%, chronic hepatitis 70%, acute hepatitis 60%. Approximately 10-20% of the general, apparently healthy population are HBsAg carriers. Although most carriers are asymptomatic, liver function studies are frequently abnormal. This study will identify approximately 1,000-2,000 apparently healthy HBsAg carrier males 40-59 years of age. These will be followed for at least five years to determine the frequency of morbidity and mortality from liver disease. The liver disease rates in these carriers will be compared with those of 9,000 to 18,000 non-HBsAg carriers selected from the same population. Familial aggregation of HBsAg and chronic liver disease is also under study.

MEDICAL SURVEILLANCE AND INTERVENTION - BLADDER CANCER
D.L. Bayliss, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (D-IARC-79-983)
As aromatic amines, specifically beta-napthylamine, benzidine, and di-chloro-benzidine, have been responsible for cancer of the bladder in up to 100 percent of workers, the continued and increasing use of such carcinogens, not only in dye and pigment production but also in pharmaceuticals, detergents, food colors and specialized chemicals, makes it imperative that surveillance should continue so that situations similar to the current bladder cancer epidemic in New Jersey be prevented. A cooperative agreement is being developed with the National Cancer Institute to place all such exposed workers under medical surveillance. This will include periodic examinations and constant follow-up to detect early changes consistent with the development of bladder cancer.

3.2209,
MORTALITY EXPERIENCE OF HOUSEHOLD CONTACTS OF ASBESTOS WORKERS

H.A. Anderson, New York University, Graduate School, *100 Washington Sq. E., New York, New York* 10003

From 1941 to 1945, 933 men were employed in an asbestos products factory in an eastern US city. Approximately 2,225 individuals lived in their households at the time of employment. This group is being identified and will form a cohort for the prospective evaluation of their mortality experience 1946-1980. It is already known that household contact disease may occur ('conjugal' asbestos disease); this information will provide quantitative information concerning the extent of that risk. Moreover, while mesothelioma is known to occur among household contacts, the risk of other disease has not been investigated. It is expected to obtain information in this regard as well. In parallel clinical studies, over 700 family contacts have so far been examined; one-third have chest x-ray abnormalities consistent with asbestos exposure. In the overall cohort more than 500 deaths have occurred including five from mesothelioma.

3.2210,
PREDICTION OF LUNG CANCER RATES BY SPUTUM CYTOLOGY

V.E. Archer, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

In assessing the lung cancer risk of a worker population, it is highly desirable to have an early prediction method so that excess risk can be detected early. For new chemicals suspected of being pulmonary carcinogens, sputum cytology may reduce by half or more the time needed to determine the existence of risk, thus possibly saving many lives. Several sputum samples from about 15,000 uranium workers have been collected over a period of 18 years. Using Dr. Saccomanno's classification, the samples will be analyzed to show correlation with age, tobacco smoking and radiation exposure. Persons with various grades of atypia will be followed to see how their sputum changes over the years, and to determine subsequent lung cancer mortality associated with each class of atypia (up to 18 years). Multiple correlation analyses will be done (utilizing support from NCI). These analyses will permit assessment of the use of sputum cytology as a survey tool assessing the lung cancer risk of a population before lung cancer has appeared.

THE PHILADELPHIA PULMONARY NEOPLASM RESEARCH PROJECT

W. Weiss, Hahnemann Medical College & Hospital, Medical College, Dept. of Medicine, *235 N. 15th St., Philadelphia, Pennsylvania* 19102

The objective of this study is to investigate the natural history of lung cancer in a population of male volunteers aged 45 and over. A total of 6,027 men was enrolled in a prospective study from December 1951 to December 1955 and followed with semi-annual chest photofluorograms and symptom questionnaires for 10 years. Medical information on all illnesses and deaths was collected. Data were placed on computer tape by 1968 and the results have been under continual analysis. A total of 121 men developed lung cancer at a rate of 2.3/1,000 man-years. The risk increased with increasing age, was higher in Non-Whites than in Whites, and bore a dose-response relationship to cigarette smoking. None of 830 non-smokers developed lung cancer. The dose-response relationship between smoking and lung cancer held true for adenocarcinoma as well as for squamous cell and small cell carcinoma, but the gradient was not as steep. The characteristics of 'early' lung cancer have been described. Screening contributed little to the survival rate. Survival factors have been described. Chronic cough was found to be an additional risk factor. During the occult phase of the lung cancer chronic cough and expectoration were found to increase prior to X-ray detection of the cancer compared with matched controls. A study of the diameter at detection and tumor volume doubling times of those cancers presenting as round nodules on X-ray sugests that the 'lead time' was almost two years on the average before such cancers would be detected as a result of symptoms. Further analysis is continuing.

EPIDEMIOLOGIC CHARACTERISTICS OF PRE- AND POST-MENOPAUSAL BREAST CANCER PATIENTS

D.C. Deubner, Duke University, School of Medicine, Dept. of Community Health & Family Medicine, *Box 3711, Durham, North Carolina* 27710

The goal is to define the epidemiological characteristics of breast cancer in pre- and post-menopausal women and to relate these characteristics to the pathobiology of the tumour as manifested by oestradiol and progesterone receptors, histology and cellular ultrastructure. This case-control study concerns breast cancer patients undergoing surgery at university and community hospitals, surgical or medical patients not having breast or gynaecological surgery at the same hospitals, and subjects from the community. Data collection is by interview of all subjects and review of charts of hospital patients. Laboratory studies on tissue and serum from breast cancer patients will include quantitative oestrogen and progesterone receptor determinations, evaluation of histology and ultrastructure by a standardized protocol, and oestrogen and progesterone serum determinations. Statistical analyses will estimate the relative strength of association between breast cancer and pre- and post-menopausal women and such factors as age at menarche, age at first delivery, obesity, and family history of breast cancer. Associations between risk factors and tumour cell biology and morphology will be sought by comparing the laboratory results in women with and without single or multiple risk factors.

TRENDS IN MORBIDITY AND MORTALITY OF UTERINE CANCER IN RELATION TO MASS CYTOLOGICAL SCREENING

W.M. Christopherson, University of Louisville, School of Medicine, Dept. of Pathology, *101 W. Chestnut, Louisville, Kentucky* 40202

A population-based registry of all uterine tumors in Jefferson County, Kentucky, has been maintained since 1953. Jefferson County has had mass cytological screening since 1956 and by as early as 1967 over 90% of the population had been screened. Morbidity and mortality trends as well as patient survival and a record of histological type have been monitored. Over the period of the study mortality from cervix cancer has decreased significantly when compared to mortality trends in United Kingdom and Ireland and in Denmark. The study continues.

3.2216,
MORTALITY AND INDUSTRIAL HYGIENE STUDY OF ALUMINUM WORKERS

D.P. Brown, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Workers in the aluminum reduction industry are exposed to a variety of substances, hydrogen fluoride fumes, dust, carbon monoxide and coal tar pitch volatiles (CTPV) such as benz(a)pyrene. CTPVs are released in the anode preparation area in plants using pre-baked anode and in the pot lines where Soderbery self-baking cells are used. The release of CTPV is thought to be termperature dependent and sufficiently high temperatures are reached in both anode preparation and electrolysis of aluminum to achieve this. Thus, there is concern for the health of aluminum workers who may be exposed to carcinogens within CTPV such as benz(a)pyrene. Industrial hygiene surveys of the aluminum reduction industry have revealed levels of CTPVs well above the current occupational health standard of 0.2 milligram per cubic meter by the benzene soluble fraction method. A variety of studies have been carried out to describe the cancer mortality experience of workers in aluminum reduction facilities. In order to fully define the specific cancer risk within the industry, a retrospective case-control study is being carried out on aluminum reduction workers. Industrial hygienists will assist in classifying job categories and in verifying related industrial hygiene data. Existing data generated from a previous study will be used. 190 lung cancer cases and 760 controls matched on date of birth, date first employed and length of employment have been selected, work histories coded, and some preliminary analyses made. Environmental measurements are being calculated for the various job titles included in the study, so that the analysis can take full advantage of exposure-response data.

SECOND PRIMARY MALIGNANCIES FOLLOWING RADIOTHERAPY OR CHEMOTHERAPY OR BOTH FOR HODGKIN'S DISEASE

G.B. Hutchison, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115

The objective is to determine whether intensive radiotherapy or chemotherapy or their combination used in management of Hodgkin's disease is the

cause of an increased incidence of secondary primary malignancies within 20 years after exposure. If an increase is found, it is desired to identify the details of the exposure responsible, the time relationships of the effect, and the spectrum of types of second malignancy. Approximately 2,000 patients with Hodgkin's disease treated in 1960 or later will be enrolled and followed for incidence of second malignancies. Patients will be ascertained through the collaboration of approximately 10 clinical centres in the United States and Canada. The study is planned as an independent test of the hypothesis derived from observations made at the National Cancer Institute, U.S.A, of an increased incidence of the total group of all malignancies. This increase is approximately 3-fold in patients given extensive chemotherapy or intensive radiotherapy and may be severalfold greater in patients given intensive courses of either therapy after relapse following an intensive course of the other therapy.

AGE-DISTRIBUTION OF LUNG CANCER IN PATIENTS AT VETERANS ADMINISTRATION HOSPITAL - HINES, ILLINOIS

H.T. Langston, Northwestern University, Chicago Campus, School of Medicine, Dept. of Surgery, *303 E. Chicago Ave., Chicago, Illinois* 60611

The age-distribution study previously reported now spans the 35 years between 1939 and 1973. As anticipated, the number of cancers contributed by the generation born between 1890 and 1900 fell off in the last quinquennial period of 1969 to 1973. This is now, after all, an aging cohort. There were 350 patients in the younger age groups (35-59 years) in the 1939 to 1943 period (90 percent of the total) and only 464 patients in the same age range in the 1969-1973 period (56 percent of the total). This supports the view that the younger cohorts are not fully replacing the older and aging generations. The total number of cases in this hospital during the 1969 to 1973 period did not increase.

ECOLOGICAL, STATISTICAL, ETHOLOGICAL, AND RELATED BIOLOGICAL STUDIES ON AIR POLLUTION, SMOKING AND OTHER ENVIRONMENTAL VARIABLES (ABBREV)

R.J. Hickey, University of Pennsylvania, Wharton School of Finance & Commerce, Dept. of Statistics, *34th & Spruce Sts., Philadelphia, Pennsylvania* 19104

Statistical and other studies are being conducted to test a four-part hypothesis that: (1) Among common air pollutant chemicals there are some that are mutagenically or otherwise hazardous to health; (2) such chemicals accelerate development of and increase risk of occurrence and mortality from chronic diseases of aging (e.g., cancer, heart disease), and also alter intergenerational DNA leading to birth defects and their consequences, in proportion to exposure; (3) chronic disease risk and resultant mortality are influenced significantly by individual genetic/constitutional characteristics; and (4) these individual characteristics also significantly influence certain behavioral physiological characteristics, such as tobacco smoking and coffee drinking. Three subsidiary hypotheses are that (5) smoking is, for many, symptomatic of physiological deficiencies that nicotine tends to alleviate, with smoking functioning partly as an example of behavioral regulation of physiological homeostasis, (6) viruses can also function mutagenically, along with certain environmental pollutant chemicals, leading to accumulation of somatic mutations, and (7) recent urban mortality rate data are more strongly correlated with air pollution levels of, say, 10 years ago than with recent levels. The basis for (7) may be a result of cumulative, and possibly multiplicative (cf. Orgel's theory), long-term effects of cell alterations inflicted by pollutant chemicals and other factors, including viruses. Methods of multivariate statistical analysis are used in these multi-regional, multi-environmental variable studies, especially an optimal subset selection (algorithm) modification of multiple regression analysis. Data used are human mortality rates for all cancers, cancers of various sites, and leukaemia, along with other chronic diseases (e.g., heart disease) for individual metropolitan populations, and environmental chemical concentration data and other environmental variable data.

HUMAN RADIATION CARCINOGENESIS STUDY

E.D. Woodard, University of Rochester, School of Medicine & Dentistry, Dept. of Radiology, *601 Elmwood Ave., P.O. Box 607, Rochester, New York* 14642

For the past 25 years the health status of the following three populations of persons given radiation treatment for benign conditions many years before has been followed: (1) 2,872 persons given x-ray in infancy for thymic enlargement and their 5,055 untreated siblings; (2) 606 women given x-ray treatment for acute post-partum mastitis controlled by 554 untreated sisters and by 539 women with a history of acute post-partum mastitis not treated with x-ray treatment and 206 of their untreated siblings; and (3) 971 persons given x-ray treatment to the head during childhood for lymphoid hyperplasia of the nasopharynx, 417 persons treated with intranasal radium capsules for the same condition and the 2,751 non-irradiated siblings of the irradiated subjects. In the thymus-irradiated series (1), an increased incidence of neoplasms and of illnesses with auto-immune features was observed over that seen in the non-irradiated siblings and in the general population. Only thyroid neoplasms occurred in sufficient numbers to permit analysis of incidence as a function of dose and other factors. Radiation-induced thyroid cancer shows a linear dose-response. Jews and females have an increased risk of developing thyroid cancer. In the breast-irradiated women (2), the incidence of breast cancer is increased over that in the controls beginning 15 years post exposure and shows a dose-response with an apparent peak at 400 r (air). A histopathological comparison review of breast cancers experienced by the irradiated women and by controls indicates no differences. A program of periodic mammographic-thermographic screening has been implemented in this series. In 1961, the head-irradiated population (3) was shown to have an increased incidence of radiation-induced neoplasms. They are being resurveyed at the present time.

REGISTRY FOR RESEARCH INTO HORMONAL TRANSPLACENTAL CARCINOGENESIS

A.L. Herbst, University of Chicago, Pritzker School of Medicine, Dept. of Obstetrics & Gynecology, *5801 S. Ellis Ave., Chicago, Illinois* 60637

The Registry has been established to collect clinical, pathological and epidemiological data on cases of clear cell adenocarcinoma of the genital tract in women born after 1940 regardless of whether or not the patient has a history of prenatal exposure to hormones, and all cases of genital cancer (vulva, vagina, cervix, endometrium, tube, ovary) in any female with a reasonable possibility of exposure in utero to any exogenous sex hormones, including steroidal oestrogens and progestins. Material for review is sought from all such cases occurring in the United States or other countries. Cases may be reported to: Registry for Research on Hormonal Transplacental Carcinogenesis, MARP 303, 5841 South Maryland Ave., Chicago, IL 60637. Pathological studies are conducted at Massachusetts General Hospital in Boston with Drs. Scully, Robboy and Welch as collaborators.

DEVELOPMENT OF STATISTICAL AND COMPUTER METHODS FOR THE ANALYSIS OF INCIDENCE AND MORTALITY DATA

J.A. Lee, University of Washington, School of Public Health & Community Medicine, Dept. of Epidemiology, *4000 15th Ave. N.E., Seattle, Washington* 98105

The aim of this continued study is to develop and make available methods for the dissection of generation, age, and time period effects from the matrices of data provided by cancer registries and vital statis-

tical systems on the occurrence of human cancer. Currently the study is in an interim phase, with separate programs for the calculation of rates and a series of fitted trend lines, and for multivariate analysis (least squares and maximum likelihood). A simplication of the system is the next goal. Papers have been published on malignant melanoma and breast cancer (male and female). Attention will continue to be concentrated on these sites.

SURVEILLANCE FOR DRUGS THAT MAY BE CARCINOGENIC

G.D. Friedman, Kaiser Foundation Research Inst., Dept. of Medical Methods Research, *1956 Webster St., Room 310 B, Oakland, California* 94612

The objective is to evaluate medicaments for possible carcinogenic effects. To seek hypotheses, 150,000 persons will be classified according to use and non-use of various medicaments by means of computer-stored records collected from 1969-1973 by the San Francisco Kaiser-Permanente Clinic (1.3 million prescriptions for 3,400 drugs). The development of various kinds of cancer will be followed up by surveillance of hospital records. Drug-cancer associations found would be subjected to further study. More detailed evaluation of hypotheses would be by case-control studies using the Kaiser-Permanente records, with attention to potential confounding variables.

CARCINOEMBRYONIC ANTIGEN (CEA) AND OTHER BIOLOGICAL MARKERS IN CANCER-PRONE FAMILIES

H.A. Guirgis, University of California, Irvine Campus, California College of Medicine, Dept. of Community & Environmental Medicine, *Irvine, California* 92664

Carcinoembryonic antigen (CEA) was studied in 224 direct-line members and 96 unrelated spouses from pedigrees manifesting the cancer family syndrome (heritable predisposition to adenocarcinomas of the colon and endometrium). Distributions of CEA per se showed Poisson-like properties and values were therefore transformed by taking square roots. Effects of age and duration of smoking were adjusted for by linear regression. Cancer patients and relatives at high genetic risk had a significantly greater mean CEA than relatives at low genetic risk. Surprisingly, unrelated spouses had mean levels of CEA which were strikingly similar to those in the corresponding cancer risk class of their direct-line mates. A highly significant intraclass correlation in CEA was also observed between the direct-line relatives and their spouses, whereas the intraclass correlation between direct-line full siblings was lower, and that between spouses of full siblings was negible. These results suggest the existence of both genetic and connubial effects on CEA in the cancer family syndrome, presumably due to a common environmental agent acting in concert with genetic predisposition to oncogenesis. A battery of biological markers were studied among high risk members of certain pedigrees, and an index of cancer risk incorporating CEA, percentage of T lymphocytes, lymphocytic transformation, aryl hydrocarbon hydroxylase, and IgA shows good potential for delineating individuals susceptible to cancer. Agreement of the observed number of aberrant index scores with the expected number of deleterious-gene carriers based upon Mendelian segregation and the age distribution of the sample provides preliminary support for the identification of cancer risk utilizing multiple biological markers. Work continues.

EPIDEMIOLOGICAL STUDIES OF CANCER IN LOUISIANA

M.S. Gottlieb, Tulane University of Louisiana, School of Medicine, Dept. of Medicine, *1430 Tulane Ave., New Orleans, Louisiana* 70112

Death certificates for cancer of the lung, nasopharynx, pancreas and bladder will be identified for selected Louisiana parishes for the years 1960-1975. Controls will be matched by parish of residence, year of death, age (within 2 years), sex and race. The frequency of occurrence of names attributable to groups with a common heritage will also be compared, as will relationship of residence at death and distance from selected industries, and water source. The objective is to determine single or multiple factors which can be identified as associated with a greater risk in cases compared with controls. This will form the basis of subsequent additional observational studies. Sub-studies on populations exposed to unique substances are included.

EPIDEMIOLOGY OF UTERINE CERVIX CANCER IN AN AREA OF LOW INCIDENCE

J.L. Lyon, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Family & Community Medicine, *1400 E. 2nd S., Salt Lake City, Utah* 84112

Over the last 20 years the State of Utah has had 25% lower mortality than the U.S.A. as a whole from cancer of the uterine cervix. Members of the church of Jesus Christ of Latter-Day Saints (Mormons) have rates of cervical cancer 50% below those of the non-Mormons in Utah. The Mormon population also has a higher fertility rate and age of marriage than non-Mormons. A case-control study to investigate the etiology of cervical cancer in both Mormons and Non-Mormons residing in the State of Utah is under way. Cases are identified through a population-based cancer registry, and controls matched for age and county of residence are identified from the general population. Cases and controls are interviewed concerning age when first married, first pregnancy, commencement of sexual intercourse, divorce, number of sexual partners, and venereal disease exposure. A preliminary report is being prepared.

LATE EFFECTS OF CANCER TREATMENT IN CHILDREN INCLUDING SECOND MALIGNANT NEOPLASMS - CHILDREN'S INTERNATIONAL CANCER INVENTORY

A.T. Meadows, University of Pennsylvania, Childrens Hospital of Philadelphia, Childrens Hospital of Philadelphia, *34th St. & Civic Ctr. Blvd., Philadelphia, Pennsylvania* 19104

As treatment for childhood cancer was becoming more successful and survivors were increasing, an interest developed in studying these children for late effects to organ systems of radiation and chemotherapy. Also of interest was the rate of second tumors in these survivors, whether treatment-related or not. Begun in 1972 at three pilot institutions, the study has been expanded to include children with cancer at 13 institutions, particularly with reference to: (1) the relationship of second malignant neoplasms (SMN) to therapy and other aetiological factors, (2) the incidence of SMN, (3) histopathology of SMN (4) survival of patients with SMN, (5) unusual tumors in children with cancer, (6) congenital anomalies in patients, (7) data regarding siblings and other family members for cancer and congenital defects, and (8) other deleterious sequelae encountered in patients cured of cancer in childhood. All studies are now active, including a case-control study of the 200 SMN in our registry to 1979.

OHIO CENTRAL DATA BASE FOR CHILDHOOD CANCER

W.A. Newton, Ohio State University, Columbus Campus, Childrens Hospital, *561 S. 17th St., Livingston Pike, Columbus, Ohio* 43205

The objective is to provide baseline information on demographic patterns for cancer morbidity and mortality in Ohio children. This includes case-finding information regarding type of cancer by age, race, sex, place of residence, staging at initial diagnosis and institution of initial diagnosis. Abstracts are being prepared on hospital discharge of all newly diagnosed children with cancer beginning January 1975 from all the major treatment centers for children in Ohio. These abstracts utilize forms currently in use in a broader data collection program, the Children's Hospital Automated Medical Program (CHAMP), a medical research computer center located in Children's Hospital, Columbus, Ohio. In addition, an epidemiological questionnaire to be completed by parents is also being collected. This includes general questions on family history, including cancer in relatives and malformations, with additional specific information on patients with leukemia, brain tumors, Wilms' tumor and malignant lymphoma.

PROPORTIONAL OCCUPATIONAL ANALYSIS USING DEATH CERTIFICATE DATA

L.D. Marrett, Connecticut Cancer Epidemiology Unit, Dept. of Epidemiology & Public Health, *30 College St., New Haven, Connecticut* 06510

Occupational data for a random sample of 8,000 Connecticut adults who died between 1959 and 1961 have been collected and coded. Occupation, industry, birthplace and cause of death for this general population sample will be compared with those of deceased Connecticut Tumor Registry incidence cancer cases. Such analyses will control for sex, age at death, and socioeconomic status. These data are currently being used in the studies of occupational factors in urinary bladder cancer and chronic leukaemia in Connecticut. It is hoped that the results of these and similar studies on other cancer sites will suggest new hypotheses regarding associations between occupational exposures and subsequent cancer experience.

EPIDEMIOLOGICAL STUDY OF ENDOMETRIAL CANCER

R.S. Paffenbarger, University of California, Berkeley Campus, School of Public Health, Dept. of Biomedical & Environmental Health Sciences, *Berkeley, California* 94720

Endometrial cancer incidence in northern California Caucasian women had been rising steadily over the last decade, at a rate considerably greater than chance expectation: hormonal influence from prior reproductive events and female hormones taken therapeutically (or prophylactically) are suspected causes. Using case-control methods, it is intended to study childbearing practices (e.g., age at first birth, child spacing, number of children, infertility, etc.), together with the use of post-menopausal and other hormones, of 900 women who develop endometrial cancer and of appropriate control women who do not. Information will be collected by hospital or home interview from study subjects living in five San Francisco Bay Area counties. We anticipate being able to identify the kinds of pregnancy and childbearing experience that distinguish those women who are at greatest risk of subsequent endometrial cancer. Relative risks will be computed for women who chose to remain childless, for those who deliberately decided on late childbearing, and for those who were unable to conceive.

DEFINITION OF EPIDEMIOLOGICAL CHARACTERISTICS OF PRE- AND POST-MENOPAUSAL BREAST CANCER

R.S. Paffenbarger, University of California, Berkeley Campus, School of Public Health, Dept. of Biomedical & Environmental Health Sciences, *Berkeley, California* 94720

Using case-control methods, interviews of Caucasian, Negro, and Oriental women in the San Francisco Bay Area, totalling over 2,500 breast cancer patients and 5,000 controls, will be conducted in the three-year period beginning July 1, 1976. Characteristics receiving special attention include age, catamenial and childbearing events, indicators of early fertility, exogenous hormone and drug use, sociocultural factors, family history of cancer, radiation exposure, truncated dietary histories, and various physical measurements. Extent of disease (staging), histological diagnoses, and survival are established. Associations between epidemiological characteristics and breast cancer (pre-menopausal vs. post-menopausal) will be sought.

Description provided by IARC and DKFZ with ICRDB/NCI support.

REPRODUCTIVE CAPACITY AND BREAST OR OVARY CANCER RISK

R.S. Paffenbarger, University of California, Berkeley Campus, School of Public Health, Dept. of Biomedical & Environmental Health Sciences, *Berkeley, California* 94720

Recent work by MacMahon et al. showed that increased risk of breast cancer in women with fewer children may be due to late age at first childbirth. Similarly, Joly et al. have shown that increased risk of ovary cancer may be due to delay in first pregnancy. A differing view could be that late childbirth or late pregnancy and carcinogenesis relate to a common hormonal aetiology. A special contribution of the study (2,250 cases of breast cancer and 900 cases of ovary cancer) is to determine whether increased cancer risk differs according to whether the late childbirth or pregnancy is due to lower fertility or to a voluntary delay of pregnancy. Since the hormonal pattern resulting from early pregnancy may not be the same as that associated with basic reproductive capacity, this case-control study, with emphasis on reasons for early or late pregnancy, will assess need for specific hormonal studies of breast and ovary cancer risk.

MORTALITY STUDIES IN RELATION TO OCCUPATIONAL EXPOSURE TO CHEMICALS

M.G. Ott, Dow Chemical Co., Dept. of Epidemiology, *220 Dow Ctr., Midland, Michigan* 48640

These studies are part of a continuing program to evaluate the relationships between occupational exposure to chemicals and cause-specific mortality. A retrospective cohort approach is followed, with potential exposure classified on the basis of industrial hygiene surveys and employee work histories. The following units are included in current studies: styrene-based products (manufacturing and research), production of nitrogenous organic dyes, a fiber production process using methylene chloride as a solvent, and a manufacturing unit with diverse chemical operations.

EPIDEMIOLOGICAL AND GENETIC STUDIES IN PROSTATIC CANCER

I.D. Rotkin, University of Illinois, Medical Center at Chicago, Abraham Lincoln School of Medicine, Dept. of Preventive Medicine & Community Health, *1853 W. Polk St., Box 6998, Chicago, Illinois* 60680

This program has assembled and is studying known and suspected epidemiological and genetic events, factors and attributes possibly related to risk of prostatic carcinoma, sorting out those which may directly or indirectly influence onset of the lesion. Additional objectives are to explore strategies for prevention and early detection of this prevalent cancer, to identify individuals at increased risk, to provide hypotheses useful in repeat studies and prospective designs, to establish a rationale for the natural history of prostatic cancer, to structure models for oncogenesis in the human prostate, and to develop an information base for clinical and population screening programs which may contribute to reduction of morbidity and mortality rates from this disease in the population. The research design is a collaborative retrospective matched-pair case-control study designed and directed by Dr. I.D. Rotkin at the University of Illinois College of Medicine with sampling at 3 cooperating institutions in 2 widely separated metropolitan areas, the West Side Veterans Administration Hospital in Chicago, Northwestern University Medical School in Chicago and the Kaiser-Permanente Medical Center in Los Angeles, providing multiple-hospital access to large populations of prostatic cancer patients and opportunity for reproducibility comparisons by institutions, by geography, by race and by socioeconomic levels; and also full studies of 500 securely diagnosed patients against 500 cancer- and BPH-free controls. Epidemiological information is obtained with interviewer-administered questionnaires and related instruments inquiring into behavioral, environmental, sociocultural, sexual, physical, psychological and clinical factors associated with risk of this carcinoma. Familial studies are conducted into 3 generations of each kinship, with patients and controls as probands, in searching for genetic influence upon initiation of oncogenesis.

FACTORS ASSOCIATED WITH GEOGRAPHICAL DIFFERENCES IN AGE-SPECIFIC CHRONIC DISEASE DEATH RATES, INCLUDING VARIOUS SITES OF CANCER

H.I. Sauer, University of Missouri, Columbia Campus, School of Medicine, Dept. of Community & Family Medicine, *M228 Medical Sciences, Columbia, Missouri* 65201

Marked race-sex-specific differences have been demonstrated in the risk of dying at ages 45-54, 55-64, 65-74, for counties and for the 510 state economic areas within the United States, as well as between portions of other countries. The geographical patterns are quite similar for various time periods, from 1949-1951 to 1968-1972. Mortality patterns for malignant neoplasms (all sites) and for lung cancer and cancer of the pancreas are correlated with death rates for the cardiovascular diseases (P less than 0.01). These patterns suggest that geographical differences in the patterns of cigarette smoking and other environmental variables may be responsible. Various techniques are being used to identify and adjust for possible shortcomings in the vital statistics data for epidemiological studies of this type. Many risk factors and suspected risk factors have been found to have statistically significant associations with the risk of dying. Several approaches are being used to test hypotheses as to the factors which are causally associated with these differences in the risk of dying and in the risk of cancer and other chronic diseases. Death rates for 1973-1976 are being compared with rates for earlier time periods, and are being used for testing the strength of various factors.

TRACE ELEMENTS AND CANCER

G.N. Schrauzer, University of California, San Diego Campus, Graduate School, Dept. of Chemistry, *P.O. Box 109, La Jolla, California* 92037

Determination of dietary intakes of trace elements in populations in different countries based on analyses

of food consumption data is being undertaken. An international data bank is being developed. Correlations between apparent dietary trace element intake and cancer mortality are being computed to test etiological hypotheses. The anti-carcinogenic effect of selenium is being explored both experimentally and on the basis of epidemiological studies. The interrelationships between diet and cancer are being investigated on the basis of the protective effect of selenium and other trace elements against cancer.

INFLUENCE OF SMOKING ON CAUSES OF DEATH AMONG ASBESTOS INSULATION WORKERS

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *1 Gustave L. Levy Pl., New York, New York* 10029

On 1 January 1967 the entire membership, 17,800 men, of the Asbestos Workers' Union in the U.S.A. and Canada was registered. Smoking habits were recorded at the time of registration. The entire group has been followed prospectively from 1967 and death rates are being calculated taking smoking into account. For smoking-specific rates, the current data derived from the American Cancer Society's Cancer Prevention Study are being utilized, since this gives smoking-specific death rates 1960-1972. By the end of 1975, more than 2,000 deaths had occurred. Analysis is being undertaken according to cigarette, pipe and cigar smoking, age at beginning to smoke, amount smoked, duration of employment and duration from onset of employment, as well as other parameters. Specific causes of death which are of interest include various types of cancer and asbestosis.

MORTALITY STUDY OF LEAD WORKERS

S.G. Selevan, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Lead phosphate administered subcutaneously to rats has resulted in the induction of renal tumors and renal tumors have also been induced in rats by lead acetate-containing diets. Lead oxide appears to act synergistically with benzo(a)pyrene in pulmonary tumorigenesis in Syrian hamsters; lead is reportedly cumulative in the lung. Workers in lead smelters and battery plants breathe or ingest lead as a result of poor hygiene. Possible carcinogenic or co-carcinogenic effect deserves examination. Although the authors of a study on cancer among lead battery plant workers concluded that their results do not support a specific cancer risk, the data suggest that such a risk may be present. In order to further assess the possible excess cancer risk to lead exposure, a further retrospective cohort study is planned on workers exposed to lead and its compounds.

ASBESTOS AND CANCER IN PATIENTS WITH LOW OR NO OCCUPATIONAL EXPOSURE

M. Warnock, University of California, San Francisco Campus, School of Medicine, Dept. of Pathology, *551 Parnassus Ave., San Francisco, California* 94122

Previous studies in this Department have failed to demonstrate a relation between numbers of asbestos bodies and the presence of carcinoma of the lung or gastrointestinal tract in workers with very low asbestos exposure. Asbestos bodies, however, represent only a part, and perhaps only a small part, of the total lung asbestos burden, which is composed of coated bodies as well as uncoated fibers. It is possible that a relation exists between numbers of uncoated asbestos fibers and the presence of bronchogenic carcinoma. This study will attempt to quantify and type the uncoated asbestos fibers as well as asbestos bodies at various sites in the lung. A new preparative method, already used for examining and identifying the nature of the cores of asbestos bodies by electron diffraction, will be used to identify further these same bodies by electron microprobe analysis. An additional preparative method has been devised for recovering uncoated asbestos fibers. Relations between numbers of coated and uncoated asbestos fibers, as well as their relative locations within the lung, will be tabulated, and an attempt will be made to correlate numbers or types of fibers with the presence or absence of carcinomas. It has previously been shown here that numbers of asbestos bodies are related to occupation; an attempt will be made to establish whether a similar situation exists for uncoated fibers or whether they are derived from the environment.

CANCER IN PERSONS EXPOSED TO EXOGENOUS ESTROGENS

F.W. Falcier, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510

The purpose of this research is to estimate the range of cancer risk from prenatal exposure to exogenous estrogens among mothers and their exposed male and female offspring. Two matched control groups of unexposed mother-offspring pairs will be identified and the cancer incidence among these groups will be compared to that in the at-risk group. One group will be based on physician-matched controls, the second control group will be selected using Connecticut birth registration data. Cancer experience will be determined by linking the names of members of the cohorts to those of patients reported to the Connecticut Tumor Registry. All cancer sites will be considered, with particular attention paid to reproductive system cancers. To date more than 1,000 exposed mother-offspring pairs and 1,000 physician matched control pairs have been identified and detailed information has been abstracted from their prenatal medical records. An additional 500 exposed pregnancies have been identified and data collection is in progress. Individual follow-up is being conducted for each mother and offspring in all cohorts.

CANCER RISKS IN COSMETOLOGISTS

J.W. Meigs, Connecticut Cancer Epidemiology Unit, *30 College St., New Haven, Connecticut* 06510

This study will investigate the incidence of cancer of all sites among cosmetologists who were licensed to practice in Connecticut before December 1965 and will provide a more definitive estimate of risk suggested by the preliminary results according to which cosmetologists may have increased risk of acute leukaemia. This extension will enlarge the study group from 12,000 to 17,000, including cosmetologists whose date of birth was previously unavailable. Follow-up status as of December 1978 will be determined for all cosmetologists. The expected number of cases of cancer by individual sites will be estimated by applying to the group at risk the cancer incidence rates of the general Connecticut population, specific for age, calendar year, sex and site. Cancer cases among the cosmetologists will be ascertained through December 1978 by computer linkage of the names in the study group with those reported to the Connecticut Tumor Registry.

SEROEPIDEMIOLOGICAL STUDY OF HERPES SIMPLEX VIRUS IN CARCINOGENESIS OF THE CERVIX

E. Stern, University of California, Los Angeles Campus, School of Public Health, Dept. of Public Health, *405 Hilgard Ave., Los Angeles, California* 90024

It is proposed to investigate by a longitudinal study a possible relationship between herpes simplex viruses (HSV), the development of cervical dysplasia, and its progression to cervical cancer. One of the critical issues is the timing of herpes infection in relation to onset of the neoplastic process and a feature of the proposed research is the serial observation and testing of patients to clarify the temporal relationship of herpes infection and carcinogenesis. In considering a longitudinal approach, the relatively low incidence of cervical cancer and the long latency present serious problems of sample size and duration of follow-up. The number of women in the study as well as duration of follow-up can be reduced by following a defined population of women who already have the cancer precursor, dysplasia of the cervix. We have been investigating the possible relationship of steroid contraceptives and carcinogenesis of the cervix by means of a long-term prospective study of women with dysplasia of the cervix. The proposed study on the role of HSV in carcinogenesis of the cervix uses this resource of clinical and laboratory data. Sera already collected from these patients will be used for serial viral antibody studies. Further follow-up of patients and collection of samples will continue.

CERVICAL CYTOLOGY PROGRAM

R.C. Steinkamp, State Dept. of Health, *4815 W. Markham St., Little Rock, Arkansas* 72205

Arkansas ranks 12th among the states of the U.S.A. with regard to mortality from uterine cervical cancer. The existence of rural communities, non-white populations and areas with low physician:population ratio constitutes high risk conditions. There is insufficient screening and follow-up. The program is designed to reach the high-risk woman by utilizing ancillary facilities in statewide local health departments, public health nurses and a system of newly developed colposcopy clinics. These clinics provide for definitive diagnosis for about 85-90% of women found to have abnormal Papanicolau smears. The program aims to follow up (1) all women with abnormalities to ascertain the course of dysplasias of the cervix and (2) all women with normal cytological smears prospectively in relation to epidemiological factors, socioeconomic status, oral contraceptives and other factors.

CARDIOVASCULAR DISEASE EPIDEMIOLOGY IN 40,000 EMPLOYED CHICAGOANS

J. Stamler, Northwestern University, Chicago Campus, School of Medicine, Dept. of Preventive Medicine & Community Health, *303 E. Chicago Ave., Chicago, Illinois* 60611

A second-generation prospective epidemiological study on hypertensive and atherosclerotic diseases, particularly coronary heart disease, is in progress to solve key unanswered questions. Almost 40,000 men and women, both white and black, chiefly 25-64 and identified in a Chicago Heart Association screening project from 1967 to 1973, are being followed for 10 years to determine mortality rates. Three other cohorts are also being followed: men aged 40-59 in 1958 and men aged 25-39 in 1959, employed by the People Gas, Light and Coke Company in Chicago and men aged 40-55 in 1958, employed by the Western Electric Company. The contributions of several variables to the risks of death are being assessed. The causes of death to be examined include lung cancer and all neoplastic diseases.

FAMILIAL AGGREGATION OF CANCER IN A MEXICAN-AMERICAN COMMUNITY

K.M. Weiss, University of Texas, Health Science Center at Houston, Graduate School of Biomedical Sciences, Dept. of Demographic & Population Genetics, *P.O. Box 20334, Houston, Texas* 77025

A closed population of Roman Catholics of Mexican/Spanish ancestry for which birth, marriage, parenthood, and death records exist from its founding in the mid-1700s to the present is being studied. These church, hospital, and civil records provide the data base for reconstructing families back to 1900 and before. Such families will be examined statistically to see if cancer mortality aggregates non-randomly among them, so as to determine heterogeneity in genetically based risk for various cancer sites. In addition, the fertility of victims of cancer will be ascertained to make short-term predictions of the proportion of cancer mortality which may be related to genetic factors. Environmental influences will be taken into account in the statistical methods used to assay the pedigrees. The age pattern of incidence for cancer, the effect of mortality from competing causes, and the changing incidence and age patterns of degenerative diseases in general, and cancer in particular, will be studied. This study will constitute both a complete cancer-epidemiological study of a rather uniform population and a cancer-genetic study.

THE EPIDEMIOLOGY OF GYNECOLOGICAL CANCER

N.S. Weiss, University of Washington, School of Public Health & Community Medicine, Dept. of Epidemiology, *4000 15th Ave. N.E., Seattle, Washington* 98105

The objective of the study is to delineate the role of exogenous hormones in the etiology of endometrial, ovarian, and vulvar cancer. All residents of selected counties in the states of Washington and Utah who developed one of these cancers during a two-year period have been identified through population-based cancer registries. Cases were interviewed and their responses compared to those of a random sample of women in the population. The interview centered on use of exogenous hormones, recall being aided by displays of commonly used preparations. Some results have been published for endometrial cancer; additional results for this and the other sites will appear in the next two years.

DESCRIPTIVE EPIDEMIOLOGY OF PRIMARY MALIGNANT BONE TUMORS, CONNECTICUT, 1935-1974

A.L. Zimmerman, Connecticut Cancer Epidemiology Unit, Dept. of Epidemiology & Public Health, *30 College St., New Haven, Connecticut* 06510

Using some 1,000 cases of bone cancer from the Connecticut Tumor Registry (1935 to 1974), a descriptive epidemiological study will be carried out in the hope that this might suggest possible aetiological factors. Secular trends for bone cancer incidence and mortality will be analysed with respect to age, sex, site of neoplasm, socioeconomic status, place of residence (urban and rural), and the geographical distribution among Connecticut towns. In addition, the different histological types will be examined for possible relationships with the above variables. Diagnostic criteria and period of diagnosis will also be studied.

ENVIRONMENTAL INFLUENCES ON CANCER MORBIDITY IN THE PITTSBURGH REGION

J.B. Andelman, University of Pittsburgh, Graduate School of Public Health, Dept. of Industrial Environmental Health Sciences, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260

This project involves the use of regression modelling techniques to determine if there are differences in cancer morbidity rates for water supplies (including sources and source types) which cannot be explained by available information concerning socioeconomic status, housing density, industrialization, etc. Specifically, the Third National Cancer Survey cancer morbidity data for 19 different anatomical sites are being regressed against census tract data aggregated by water utility service areas. Residuals from these regressions are cross-classified separately with water service areas, water sources, and water source types to determine if the residuals are independent of these major water classifications.

GENETIC EPIDEMIOLOGY OF CANCERS AND OTHER MAJOR CHRONIC DISEASES

R.R. Williams, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Internal Medicine, *1400 E. 2nd S., Salt Lake City, Utah* 84112

Genetic predisposition and environmental influences are frequently suspected of acting either alone or, probably more often, together to result in the occurrence of cancer and other major chronic diseases (such as coronary artery disease). From geneological records of the Latter-Day Saints (LDS) Church (Mormons) in Salt Lake City a computerized pedigree file with 4-8 generations for a large proportion of Utah residents (75% LDS) is being constructed. Computer files of medical data including a 10-year computer file of incident tumour cases in the state of Utah and a 20-year file of death certificates are being linked to the pedigree file. Analyses will be performed to (a) estimate heritability of specific cancers (and other chronic diseases), (b) identify specific families with strong genetic predispositions, (c) elucidate specific genetic transmission mechanisms with environmental factors taken into account as penetrance functions. Major cancer sites include breast, lung, colon, prostate, and all other major sites.

GENETIC EPIDEMIOLOGY AND NATURAL HISTORY OF BREAST CANCER

N.L. Petrakis, University of California, San Francisco Campus, School of Medicine, Dept. of Epidemiology & International Health, *551 Parnassus Ave., San Francisco, California* 94122

Epidemiological and experimental studies are underway to investigate host, agent and environmental factors associated with breast cancer. A working model has been developed that relates epidemiological evidence linking reproductive experience and the risk of breast cancer to our findings regarding breast secretory activity in different groups and evidence of secretion of exogenous substances through the breast. Current research focuses on genetic markers associated with breast cancer, cytopathologic characteristics of normal and malignant breast tissue, metabolic activation of mutagenic agents by breast tissue, and secretion of potentially carcinogenic substances in breast fluid. In addition, a study of women's beliefs and health practices concerning breast cancer is underway.

STATISTICAL ANALYSIS AND QUALITY CONTROL (SAQC) CENTER FOR A CENTRALIZED CANCER PATIENT DATA SYSTEM (CCPDS)

P. Feigl, Fred Hutchinson Cancer Research Center, Program in Epidemiology & Biostatistics, *1124 Columbia St., Seattle, Washington* 98104 (D-IARC-79-1066)

The basic task to be performed by the SAQC/CCPDS project is to plan, develop, implement and operate a computerized system to deal with uniform acquisition, quality control, storage, retrieval, and analysis of basic cancer patient data submitted quarterly by 20 comprehensive cancer centers located throughout the United States. Accomplishments include: the establishment of a minimum cancer patient dataset used in common by all participating institutions; the development of training programs to assure a uniform interpretation of each item in the dataset from each institution and the assembling of computer hardware and software for editing and storing abstracts of approximately 50,000 diagnosed tumors each year. Quarterly summaries on the cumulated data, as well as special detailed reports on topics of interest to oncologists and cancer epidemiologists are provided to each participating institution. The SAQC Center is also coordinating collaborative research among the cancer centers in the etiology of male breast cancer, estrogen receptors and female breast cancer prognosis, and secular trends in osteosarcoma.

PSYCHODYNAMICS OF CANCER

R.S. Picard, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *510 E. Stoner Ave., Shreveport, Louisiana* 71130

The main objective of this study is to collect psychosocial and environmental data on groups of patients hospitalized in a General Medical Center (the Veterans Administration Hospital, Shreveport, Louisiana). The groups to be compared are: (1) non-alcoholic, non-cancerous smokers, (2) non-alcoholic, non-cancerous non-smokers, (3) alcoholic smokers, (4) alcoholic non-smokers and (5) patients with lung cancer. The data being collected from a structured questionnaire consists of (1) family history of cancer and alcoholism, (2) birth order and age difference between adjacent siblings, (3) childhood experiences, (4) present day smoking and drinking habits, (5) exposure to suspected carcinogens and (6) general demographic data. Individuals are also being asked to answer pertinent questions from the Bahnson Psychosocial Scale. Psychological data are being subjected to statistical analysis. Information from 658 case studies has been placed on punch cards and from these transcribed to magnetic tape. Of these,

471 have been separated into five groups, all over 35 years of age: (a) 116 controls who are still smoking, (b) 68 controls who have stopped smoking for a period longer than 5 years, (c) 92 non smokers, (d) 118 alcoholic smokers from a general medical ward, and (e) 77 cases of lung cancer. Preliminary item analyses are being done on 27 parameters to determine significant differences, if any, among the 5 groups. Later approximately 75 more items will be examined. The remaining 197 cases which comprise of individuals primarily under 35 years of age, but also non-smoking alcoholics, patients with cancer of other sites, and alcoholics in alcoholic units of the hospital will be investigated if significant data have been unearthed on the first set of analyses.

A RECORD LINKAGE FEASIBILITY STUDY TO OBTAIN PREVALENCE AND INCIDENCE RATES FOR MULTIPLE MYELOMA IN US VETERANS

A.Z. Keller, U.S. Veterans Admin., Dept. of Medicine & Surgery, Regional Office, Research Service, *941 N. Capitol St. N.E., Washington, District of Columbia* 20421

Since all veterans with multiple myeloma, as for most diseases, are not seen in veterans hospitals, incidence and prevalence rates derived from data on hospitalized patients are underestimated. The present study investigates the feasibility of obtaining medical information on veterans from non-veterans hospital sources to merge with data from veterans hospitals. Information will be obtained from cancer registries, hospital records and death certificates in six geographical regions to permit computation of absolute rates of multiple myeloma by race, age, and geographical area. The denominators for these rates will be veterans living in these areas as reported by the United States Census Bureau. Environmental exposures will be studied in an effort to explain observed rate disparities by race, age and geography.

TOBACCO AND ALCOHOL USAGE, MARITAL STATUS, RELIGION AND OCCUPATION AS RISK FACTORS AMONG CIRRHOTICS AND NON-CIRRHOTICS WITH CANCER

A.Z. Keller, U.S. Veterans Admin., Dept. of Medicine & Surgery, Regional Office, Research Service, *941 N. Capitol St. N.E., Washington, District of Columbia* 20421

This study is based on a 100 percent sample of 286 males with liver cirrhosis and cancer and a 2 percent sample of 374 males with cancer only who were discharged from the nationwide complex of United States veterans hospitals in a one year period. Cirrhotics and non-cirrhotics with cancer are compared in order to determine: 1) Whether the site distributions and relative risks of cancer are remarkably different by the amounts and types of alcohol consumed or tobacco smoked; 2) whether there are gradient shifts in the relative risks of cancer from one tissue or organ to another, when the uses of tobacco and alcohol range from the least to the greatest amounts; 3) whether the relative risks of cancer by anatomical sites are significantly different in relation to marital status, religion and occupation; and 4) whether, histologically and anatomically, multiple primary cancers are in excess.

EPIDEMIOLOGICAL STUDY OF BENZENE EXPOSED WORKERS

N.K. Weaver, American Petroleum Inst., Dept. of Medicine & Biological Science, *2101 L St. N.W., Washington, District of Columbia* 20037

The objective of the study is to determine the mortality rates of workers exposed to benzene in petroleum operations. Workers having known exposures to benzene will be identified, and their mortality rates determined and compared with those of other groups. Secondary studies will include proportionate mortality from pooled company records; a study of effects on health, particularly blood counts, as they relate to benzene exposure; development of a job title dictionary for exposure dosage; and establishment of a prospective medical mortality and environmental study. If primary studies reveal excess mortality from specific diseases, especially leukaemia, latency periods, dose relationships and host factors will be studied.

MORTALITY-MORBIDITY STUDY AND TUMOR REGISTRY FOR PETROLEUM, REFINING, PETROCHEMICAL AND RESEARCH AND DEVELOPMENT WORKERS

N.K. Weaver, American Petroleum Inst., Dept. of Medicine & Biological Science, *2101 L St. N.W., Washington, District of Columbia* 20037

The objective of this study is to conduct a comprehensive prospective epidemiological investigation among petroleum industry workers as a means of determining possible health consequences of occupational exposure. A data gathering, reporting, and interpreting system appropriate for the conduct of a continuing epidemiological study will be established. Patterns of morbidity (illness), mortality and tumor occurrence will be identified and compared with the rates for a suitable control population. Relationships between morbidity and mortality patterns will be related to occupational characteristics, and trends in affected worker populations will be defined. The data received from participants will be analyzed and interim reports to each individual company on its own material made. The project will encompass all disease categories in the International Classification of Diseases and the morbidity portion of the study will be based on all sickness absences of five or more days' duration.

REGISTRY OF AN X-LINKED RECESSIVE LYMPHOPROLIFERATIVE SYNDROME

D.T. Purtilo, University of Massachusetts, Medical School at Worcester, School of Medicine, Dept. of Pathology, *55 Lake Ave. N., Worcester, Massachusetts* 01605

The X-linked recessive lymphoproliferative syndrome is characterized by X-linked recessive immunodeficiency to the Epstein-Barr virus with subsequent agammaglobulinemia, fatal infectious mononucleosis, and malignant lymphoma (including Burkitt's lymphoma) in affected males. Cases of this syndrome are registered to establish diagnostic criteria and investigate the immunopathogenesis of the B cell phenotypic expressions using immunological, virological, pathological, genetic and metabolic techniques. Referrals of possible cases from colleagues for diagnosis and comprehensive studies of surviving family members are welcome.

CERVICAL CYTOLOGY DEMONSTRATION PROJECT FOR SOUTHWESTERN AMERICAN INDIAN POPULATION

S.W. Jordan, University of New Mexico, School of Medicine, Dept. of Pathology, *University Hill N.E., Albuquerque, New Mexico* 87131

The objective of this study, in addition to providing cytological diagnostic services to a large group of American Indians and selected non-Indians, is to investigate certain epidemiological aspects of uterine cervical and endometrial cancer. Previous work has shown significant differences in histologically established age-specific rates of cervical carcinoma between Southwestern American Indians and Caucasians, and this work will be extended and amplified. Also to be examined will be the effect of cytological screening on mortality rates for cervical carcinoma. Non-Indian patients attending the University of New Mexico teaching hospital and clinics serve as the control group. Records of about 140,000 patients are currently available in cytology laboratory files in machine-retrievable format.

FAMILIAL AND GENETIC FACTORS IN MALIGNANCIES

J.J. Mulvihill, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Clinical Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205

OBJECTIVES: To document the occurrence of patterns of family aggregation of neoplasms. To study such families by genetic and laboratory investigations, in an effort to elucidate the degree to which heredity and/or the common familial environment contribute to the aetiology of neoplasms. To distribute tissue and blood specimens from such families to interested laboratory investigators, for aetiologic study by cytogenetic, immunological, viral and tissue culture methods. To identify genetic factors and disorders associated with cancer.

METHODS EMPLOYED: Interview of cancer patients with respect to family occurrence of cancer and other disorders, as well as information on prior medical and environmental history; documentation of history by obtaining appropriate vital records and hospital charts; collection and distribution of biological specimens from such families; review of hospital records of series of patients with selected genetic diseases or neoplasms; survey of childhood cancer death certificates in the U.S. since 1960 to identify sib aggregation.

STATISTICAL DATA MANAGEMENT AND COORDINATING CENTER FOR THE TYLER TEXAS ASBESTOS WORKERS PROGRAM

V.F. Guinee, University of Texas, University of Texas System Cancer Center, M.D. Anderson Hospital & Tumor Inst., Dept. of Epidemiology, *6723 Bertner Ave., c/o Texas Medical Ctr., Houston, Texas* 77030

The National Cancer Institute has established a complete medical surveillance program for a group of individuals who were exposed to amosite asbestos fibers in the course of their employment at a pipe insulation manufacturing plant in Tyler, Texas. The surveillance program is a collaborative effort, with the two primary components being the Tyler Asbestos Workers Program (TAWP) affiliated with the University of Texas Health Center at Tyler and the Statistical Data Management and Coordinating Center (SDMCC) directed through the Dept. of Epidemiology, the University of Texas System Cancer Center. The primary goal of TAWP is to make medical and scientific expertise and technology available to the

affected workers and to study the pathogenesis and early detection of lung cancer induced by asbestos. The SDMCC is responsible for data collection and analysis of the total program, with particular interest in the epidemiological, laboratory and clinical data produced by TAWP/SDMCC activities.

STUDIES ON THE POSSIBLE VIRAL ETIOLOGY OF HUMAN MALIGNANCIES

J.L. Melnick, Baylor College of Medicine, School of Medicine, Dept. of Virology & Epidemiology, *1200 Moursund Ave., Houston, Texas* 77025

Serum samples of patients with cervical cancer and matched non-cancer control women are examined for antibody to individual HSV-2 induced antigens. The study attempts to answer the following questions: (1) Is there an increase in the capacity to react with HSV non-structural antigens? (2) What is the significance of finding HSV-induced DNA-binding proteins in biopsy-obtained cells of women with severe dysplasia and carcinoma?

ANOVULATION AND BREAST CANCER EPIDEMIOLOGY

R.B. Wallace, University of Iowa, School of Medicine, Dept. of Preventive Medicine & Environmental Health, *Jessup Hall, Iowa City, Iowa* 52240

The objective of this study is to empirically investigate the onset of breast cancer. Hormonal characteristics of various menstrual cycle patterns have also been measured to develop a pathophysiological hypothesis to explain some of the known breast cancer risk factors. The basic study is being performed in two phases. The first is a review of the breast cancer cases occurring in a cohort of women with concurrently collected menstrual cycle pattern, over a 45-year period, to see if women developing breast cancer can be discriminated from the others. Particular emphasis is placed on menstrual cycle patterns around menarche, menopause, and birth events. Preliminary analyses include relationship between breast cancer risk factors, ponderosity and menstrual cycle patterns. Women with early-age-at-menarche have a greater relative weight as an adult and also acquire regular menstrual cycle patterns at an earlier age. Ponderous adult women have had more cycle variation in the early years of menarche that women with a lower relative weight. The relationship between ponderosity, menstrual cycles and age-at-first-birth is variable. Women with late menopause have a greater relative weight and more menstrual cycle variation in the years prior to the menopause. Greater relative weight and increased menstrual cycle variation at all ages have been shown to be related to increased relative estrogenicity. Work is proceeding in identifying empirical menstrual cycle characteristics and subsequent actual incidence of breast cancer. No associations were found between breast cancer and manifestations of gonadal hormone activity such as menopausal hot flushes, presence of excess facial hair, and other features of body habitus. In keeping with the parity experience, breast cancer patients have different early patterns of sexual activity compared to controls. Work in all areas is progressing.

RELATIONSHIPS OF HUMAN AND BOVINE LEUKEMIA

K.J. Donham, University of Iowa, Inst. of Agricultural Medicine & Environmental Health, Dept. of Preventive Medicine & Environmental Health, *Oakdale Campus, Oakdale, Iowa* 52319

The epidemiological relationships of human leukemia and bovine lymphosarcoma in Iowa over the past three years have been studied. An excess of acute lymphocytic leukemia (ALL) in males, primarily in the most rural counties of Iowa, was found. There is also a statistically significant correlation of numbers of dairy cows and ALL in males. There is an even greater risk ratio in those counties where cases of bovine lymphosarcoma have been documented. Future research will deal with the refinement of the risks associated with human ALL and the rate of infectivity of the dairy cow population with Bovine Leukaemia Virus (BLV). A serological test will be performed on designated dairy cow populations and data from the Iowa Cancer Registry will be compared. An area that appears to have an excess of cancers will also be studied. This area also happens to be high in dairy cattle density. Various occupational and environmental factors will be studied to see if a relationship can be identified.

HEALTH STUDY OF PLUTONIUM WORKERS

G.L. Voelz, University of California, Central Office, U.S. Dept. of Energy Los Alamos Scientific Lab., Health Division, *P.O. Box 1663, Los Alamos, New Mexico* 87545

Past and present plutonium workers from six major United States nuclear installations will be followed to determine age-specific mortality rates from all major causes of death, with special emphasis on cancer. Dose-response relationships will be estimated using systemic body burden data from urine tests. The study population, approximately 20,000 individuals, will include all workers with estimated body burdens above one nanocurie, exposed workers with lesser or no body burdens, and random samples of non-exposed workers from the same installations. A cancer incidence study will be undertaken upon a subset of the study population; questionnaire studies of cardiovascular and chronic respiratory morbidity will also be carried out in that subgroup.

EPIDEMIOLOGY OF CANCER IN ADVENTISTS - A LOW RISK GROUP

R.L. Phillips, Loma Linda University, School of Health, Dept. of Biostatistics & Epidemiology, *Loma Linda, California* 92354

Seventh-Day Adventists (SDAs) are a conservative religious group who do not smoke or drink by church prescription. For most cancers unrelated to smoking, the age-sex adjusted mortality is 50-70% of the general population. The SDA Church strongly discourages use of coffee, caffeine beverages, highly refined foods and hot spices, recommending low-fat, high-fiber lacto-ovo-vegetarian diet, as well as vigorous exercise. However, apart from smoking and drinking, there is great variation in the degree of adherence to these habits making SDAs an ideal population to investigate the role of diet and other lifestyle characteristics in cancer. Further, the great variation in duration of exposure and age at first exposure to the SDA lifestyle provides an opportunity to determine the effect of lifestyle patterns early vs. late in life, as well as the effect of short term vs. long term patterns of living. This on-going prospective study seeks to (1) confirm with incidence data the previously observed low cancer mortality among SDAs and (2) determine the specific components of the SDA lifestyle which account for their apparent low risk of non-smoking-related cancers. Collection of baseline demographic data from 61,258 California SDAs, as well as detailed lifestyle characteristics from 46,000 of these, is nearly complete. In 5 more years an average 8.5 years of follow-up for the 61,258 subjects with completed questionnaire data (525,412 person-years) will be achieved. After adjusting for the expected low incidence, a probable 2,481 new cancer cases (464 colorectal, 389 breast) will be identified by reviewing records of all hospitalizations reported during annual contact with each subject. After accounting for confounding factors, comparison of site specific cancer incidence between SDAs vs. the general population (as well as among subgroups of the SDA population with differing dietary and/or lifestyle characteristics) is likely to identify new (or confirm suspected) lifestyle changes.

FOLLOW-UP STUDY OF PATIENTS TREATED BY X-RAY EPILATION FOR TINEA CAPITIS

R.E. Albert, New York University, School of Medicine, Dept. of Environmental Medicine, *100 Washington Sq. E., New York, New York* 10003

Children treated for tinea capitis between 1940 and 1959 at a major New York City dermatology clinic have been followed to examine the tumourigenic effects of X-radiation to the head (300 - 400 R). Some 2,215 irradiated patients and 1,395 patients given medications for tinea capitis have been traced. The groups are very well matched on sex, race, age and socioeconomic status. A third survey of these groups (average interval since tinea treatment - 20 years) is in progress and is showing a continued excess of basal cell carcinomas, and brain, thyroid and parotid tumors in the irradiated group.

CANCER IN PHYSICIANS - A COMPARISON WITH LAWYERS

M.G. Curnen, Columbia University, School of Public Health, Dept. of Epidemiology, *600 W. 168th St., New York, New York* 10032

This study is testing the hypothesis that physicians may be at an increased risk of dying with cancer because of their exposure to carcinogens in the milieu in which they work. Their mortality experience is being compared with that of lawyers who, in the USA, share the same lifestyle and socio-economic status. Professionals from both groups were either licensed to practice medicine or were admitted to the Bar in the State of Connecticut during the 1900-1975 period. A total of 11,527 male physicians and 6,318 male lawyers have been identified and followed until 1975. All sites of cancer are being investigated since the potential carcinogenicity of infectious agents, chemicals and radiation may affect different target organs. Age-specific mortality rates within five year age categories for physicians and lawyers grouped according to birth cohorts were computed by the modified life table method. The cancer mortality experience of physicians is further being analyzed according to specialities practiced during life.

EPIDEMIOLOGY OF CERVICAL CANCER - CHLAMYDIAE AND HERPES

J. Schachter, University of California, San Francisco Campus, George W. Hooper Foundation, *551 Parnassus Ave., San Francisco, California* 94122

The goal of this project is to determine whether any of the infectious agents under study are specifically associated with cervical cancer or dysplasia. Prevalence rates will be determined for infection with chlamydiae (bedsoniae) - particularly trachoma-inclusion conjunctivitis (TRIC) agents and herpesvirus hominis (HVH) in the cervixes of women examined at the University of California, San Francisco. Those included in these studies will be normal women (routine examination and birth control advice), women being seen for genital tract inflammatory disorders (such as cervicitis and vaginitis), women being examined at the dysplasia clinic, and women who have once had cervical cancer. Isolation attempts will be made, with cervical scrapings taken at the same time as Papanicolaou smears. Serological studies will also be carried out in an effort to obtain evidence of any prior infection with herpes and TRIC agents. Rates of serological positivity for HVH-2 and TRIC agents will be directly compared for women with cervical cancer or dysplasia. Serological results will also be compared for patients with cervical cancer or dysplasia and for normal controls. These controls will be matched with patients by age, race, and several measures of sexual experience. In addition the various indices of sexual experience in patients with dysplasia or cervical cancer and in the controls will be compared.

METABOLIC EPIDEMIOLOGY OF COLON CANCER

B.S. Reddy, American Health Foundation Inc., Division of Nutrition, *Hammond House Rd., Valhalla, New York* 10595

The overall objective of this project is to develop key biochemical and/or microbial indicators which (1) distinguish high and low risk members of cancer families for development of colon cancer and (2) study the mechanism of cancer development in this high risk population. To achieve these objectives, feces from members of cancer families (50 colon cancer-prone symptomatic and 50 colon cancer-prone asymptomatic persons) and 50 age- and sex-matched healthy spouse controls will be analyzed for bile acids, cholesterol and its metabolites, B-glucuronidase, 7-dehydroxylase, cholesterol dehydrogenase and mutagens. The aim is to explore systematically the key metabolites by which a high-risk group for colon cancer is identified and characterized.

CANCER IN ILLINOIS

S.S. Epstein, University of Illinois, Medical Center at Chicago, School of Public Health, Dept. of Occupational & Environmental Medicine, *Box 4348, Chicago, Illinois* 60680

The aim of this project is to investigate the contribution to cancer mortality of specific industrial manufacturing and processing activities in Illinois. Maps depicting mortality rates by county for Illinois on the basis of 1970-1976 data will be constructed. Major sources of carcinogens will be identified. Emissions data, ambient sampling, and dispersion models will be used to estimate levels of ambient exposures to carcinogens at different sites near the sources. Death certificates will be analyzed in order to compute mortality rates for cancer of several sites in tracts near the carcinogen sources. The tracts will be selected to control for confounding variables as much as possible. The relationship between cancer mortality rate, tract, and ambient exposure will be investigated. Possible carcinogen sources include: oil refineries, steel mills, metal refineries, chemical plants, and areas of high use of agricultural chemicals.

POSSIBLE ASSOCIATION OF DIETARY FACTORS AND NON-CONTRACEPTIVE EXOGENOUS ESTROGENS WITH BREAST CANCER

A.M. Nomura, Kuakini Medical Center, Dept. of Pathology, *347 N. Kuakini St., Honolulu, Hawaii* 96817

A case-control study of breast cancer is seeking possible associations of the disease with the use of exogenous estrogens in post-menopausal women, and with histories of dietary intake high in animal protein and fat. The study design entails a comparison of breast cancer cases with neighborhood and hospital controls in three populations who differ greatly in their risks for breast cancer: Caucasians in Hawaii, Japanese Americans in Hawaii and indigenous Japanese in Fukuoka, Japan. Two hundred cases and their matched controls will have been analyzed for each of the three populations at the end of this projected five-year study.

MICROBIOLOGICAL FACTORS CONTRIBUTING TO COLON CANCER

H.F. Mower, University of Hawaii System, Manoa Campus, John A. Burns School of Medicine, Dept. of Biochemistry & Biophysics, *2444 Dole St., Pacific Biomedical Res. Ctr., Honolulu, Hawaii* 96822

Chemical causes of colorectal cancer are being sought by the use of a bacterial mutagen assay to detect potential carcinogenic substances in human fecal samples. Preliminary epidemiological work has been done on the frequency of mutagens in feces of Japanese in Japan and Japanese in Hawaii, populations of low and high risk for large bowel cancer, respectively. Five classes of faecal mutagens have been discovered, four of them present in higher amounts in the high risk Hawaiian Japanese than in the low risk Japanese population. Two of these four mutagens are closely associated with the fecal transnitrosase. This is an enzyme which the investigators have discovered in certain strains of E. coli, various fecal bacteria and in human colon and stomach tissue. This enzyme can transfer nitroso groups from a wide variety of nitrosamines to a diverse group of amide acceptor molecules, such as simple primary and secondary amides, ureas and urethanes. The structure of the product is unknown but different from the structure of the N-nitroso-N-alkyl amides, ureas or urethanes. All products are direct acting mutagens on the Ames Salmonella strain TA98. The enzyme is increased when beef is added to the diet of man or experimental animals. The identification and structure of these products will be studied. A newly discovered enzyme, mutagen suppressor enzyme, is also present in fecal bacteria. The enzyme will specifically destroy the product of the transnitrosase, converting these substances into N2, esters, or NO2 and the original acceptor molecule. Mutagen formation is thereby prevented. Both enzymes will be purified, characterized and studied. Mechanisms whereby diet and environmental effects alter the fecal mutagens, fecal transnitrosase and fecal mutagen suppressor enzyme will be sought.

INVESTIGATION OF HISTOLOGICAL TYPES OF LUNG CANCER AMONG WOMEN IN THREE ETHNIC GROUPS IN HAWAII

M.W. Hinds, University of Hawaii System, Manoa Campus, Cancer Center of Hawaii, Epidemiology Program, *1997 East West Rd., Honolulu, Hawaii* 96822

This study will determine the histological type-specific incidence rates for lung cancer among Japanese, Chinese and Hawaiian/part-Hawaiian female residents of Hawaii and examine the association of cigarette smoking with lung cancer for each histological type and within each ethnic group. All available hospital records and pathology slides for the approximately 310 Japanese, Chinese and Hawaiian/part-Hawaiian women diagnosed with primary lung cancer during 1968-1977 will be reviewed. Pathology slides will be reviewed by two pathologists in a blind fashion, using standard histological criteria. Smoking history will be obtained from the medical records and estimates of the relative risk caused by smoking for each histological type of lung cancer will be made by comparison to a control group matched for sex, age, ethnic group and census tract of residence.

CANCER OF THE BREAST, ENDOMETRIUM, AND OVARY

H.W. Ory, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Evaluation Division, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333 (01258)

This is a large cooperative case-control study, designed to: (1) estimate the effect of oral contraceptive use on the risk of breast, endometrial, and ovarian cancer, especially among women with characteristics such as (a) oral contraceptive use in the presence of benign breast disease and other breast cancer risk factors (family history of breast cancer, etc.), (b) oral contraceptive use prior to first birth, (c) use of sequential compared to combination oral contraceptives and (d) prolonged total use of oral contraceptives; (2) evaluate the pathological nature and prognosis of breast, endometrial, and ovarian cancer which occurs in association with oral contraceptive use when the association appears causal. It is planned to examine up to as many as 10,000 cases of the three diseases combined. Cases will be drawn from population-based tumor registries and the controls will also be population-based.

TETRACHLOROETHANE EXPOSURE AND SUBSEQUENT MORTALITY FROM CANCER IN U.S. ARMY VETERANS OF WORLD WAR II

J. Norman, National Academy of Sciences, National Research Council, Medical Follow-Up Agency, *2101 Constitution Ave. N.W., Washington, District of Columbia* 20418

Heavy exposures to chemical hydrocarbons in man result mostly from industrial chemicals and pesticides, but most exposures are recent and do not lend themselves to epidemiological investigation. One member of this class of compounds, tetrachloroethane, has had wide industrial use and was also used by the Army during World War II in the impregnation of clothing against mustard gas. One-fourth of the 39 Army Chemical Processing Companies used tetrachloroethane as a solvent in the impregnation process while the remainder used an improved process in which water replaced this compound. Cases and controls are thus defined on the basis of company assignment and military speciality. The mortality experience of some 13,300 men (cases and controls) is being studied to determine the effect of exposure to the chemical on cancer mortality.

CANCER AND STEROID HORMONES

H.W. Ory, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Evaluation Division, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333

Hormones are suspected of being related to breast, ovary and endometrial cancer. However, the exact nature of this interrelationship has not been worked out completely. This prospective case-control study aims to assess the interaction of oral contraceptives and estrogenic hormones with risk factors of breast, ovary and endometrial cancer to determine if the factors operate independently, synergistically or not at all in producing the three cancers. The pilot phase of the project is currently under way. One hundred cases will be assessed to make sure that the methods intended for use work. Following this, a much larger study, to examine perhaps up to as many as 10,000 cases of the three diseases combined, is planned. The cases will be drawn from population-based tumor registries and the controls will be population-based also.

STUDY OF OVARIAN CANCER IN GREATER WASHINGTON

L. McGowan, George Washington University, School of Medicine & Health Sciences, Dept. of Obstetrics & Gynecology, *2121 Eye St. N.W., Washington, District of Columbia* 20037

In order to gain understanding of the apparently complex etiology of cancer of the human ovary, the National Cancer Inst. (NCI) will design and oversee an interview study of incident cases of ovarian cancer diagnosed in hospitals in the Washington, D.C. metropolitan area and controls discharged from the same hospitals. Although this form of malignancy is relatively common (17,000 cases per year in the U.S.) and is often fatal (10,000 deaths per year), very little is known of its causes. In the past decade, studies have clearly shown that the disease is associated with infertility and low fertility, but the mechanism remains to be elucidated. The existing suggestions of viral factors, of exogenous estrogenic factors, and of specific industrial exposures need further pursuit. NCI will conduct the study in collaboration with a local investigator experienced in the operation of an interview study of ovarian cancer, who will obtain the cooperation of the area hospitals and supervise the study staff. The study staff will be responsible for the identification of cases and controls, the interview of respondents, and the coding of data. NCI will design the protocol and the questionnaire, monitor the progress of the study, analyze the data, in cooperation with the collaborating investigator. A preliminary report has been published in Gynecologic Oncology 7, 1979.

FOLLOW-UP STUDY OF LIVER CIRRHOSIS

A.Z. Keller, U.S. Veterans Admin., Dept. of Medicine & Surgery, Regional Office, Research Service, *941 N. Capitol St. N.E., Washington, District of Columbia* 20421

More than 10,000 males with liver cirrhosis, divided into categories of age and race, will be followed up over a five to ten year period to determine their overall mortality experience, their site-specific rates of cancer incidence and their cancer risks in relation to levels of tobacco smoked and alcohol consumed. Cirrhotic patients will also be compared with a control group of the same age and race, but without liver cirrhosis, in order to evaluate differences in marital status, religious preference, residence and occupation. Controls and cases will be selected from the 171 United States veterans hospitals located in 48 contiguous states, the District of Columbia and Puerto Rico. This study is a sequel to many previous studies on United States veterans which, generally, found increased risks of floor of mouth, uvula and soft palate, pharynx, esophagus and liver cancers among cirrhotics, heavy smokers, heavy drinkers or among patients with combinations of these attributes.

ALCOHOL, TOBACCO AND AGE FACTORS IN THE RELATIVE FREQUENCY OF CANCERS AMONG MALE NEGROES WITH AND WITHOUT LIVER CIRRHOSIS

A.Z. Keller, U.S. Veterans Admin., Dept. of Medicine & Surgery, Regional Office, Research Service, *941 N. Capitol St. N.E., Washington, District of Columbia* 20421

Because ethnic factors contribute to distinct distributions of many diseases in the United States and can frequently explain still other factors in their etiology, and because, further, a recent study yielded substantial data on white cancer patients with and without liver cirrhosis, there is a decided need for comparable data on Negroes. These data will facilitate valid racial comparisons in regard to tobacco and alcohol consumption, cancer sites and age disparities among males, with and without liver cirrhosis, and may delineate factors in cancer etiology which are specific to one race. Negro cases (with liver cirrhosis and cancer) and Negro controls (with cancer but not liver cirrhosis) from the 171 veterans' hospitals in the United States will be examined over a six year period. This research will endeavor to demonstrate the extent to which cirrhotics manifest significant excesses of specific digestive organ, oral cavity and pharyngeal cancers with regard to types and amounts of tobacco smoked and alcohol consumed. The probable roles of some occupational exposures in the pathogenesis of cancers in cirrhotics will also be assessed. Subsequent analyses will entail the comparison of data on Negroes with data, already published, on 286 white males with liver cirrhosis and cancer and on 374 white males with cancer only.

THE EPIDEMIOLOGY OF MULTIPLE MYELOMA IN UNITED STATES VETERANS

A.Z. Keller, U.S. Veterans Admin., Dept. of Medicine & Surgery, Regional Office, Research Service, *941 N. Capitol St. N.E., Washington, District of Columbia* 20421

The specific aims of this research are to determine overall rates of multiple myeloma incidence by race and age, and the specific incidence rates in each state and region of the United States by race among US males, diagnosed and treated in the 171 veterans hospitals located throughout United States. This study will also determine if significant rate differences can be explained by either patterns of hospitalization or ratios of multiple myeloma patients to all other hospitalized patients by age, race and residence. The probable role of climatic factors in the incidence of multiple myeloma in each region will also be evaluated, in addition to occupational exposures, tobacco use and alcohol consumption. The multiple myeloma cases will comprise three year 100 percent sample of male discharges from United States veterans hospitals. Controls (matched to the cases on age, race and bed-sections in the hospitals) will be employed and the denominator for rates will derive from US Census Data on veterans, finally, with multivariate techniques, the contributions of age, residence, birthplace, bed-sections in hospitals, tobacco use, alcohol consumption, occupations and possibly seasonality to any marked disparity in multiple myeloma incidence by race will also be made.

CANCER MORBIDITY AND MORTALITY IN A ZONE OF CENTRIFUGAL SPREAD NEAR PESTICIDE FORMULATING PLANTS

E.P. Savage, Colorado State University, Inst. of Rural Environmental Health, Epidemiologic Pesticide Study Center, *Spruce Hall, Fort Collins, Colorado* 80523

In recent years, the association between exposure to pesticides and the resulting health effects has been investigated. Much of this research has focused on the potential carcinogenicity of the chlorinated hydrocarbons. The effects of contamination of the areas surrounding pesticide formulating plants will be investigated in this study. It is reasonable to assume that the adjacent area, and also the area affected by the meteorological dispersion of contaminants, will experience a higher level of pesticide exposure than those areas outside this zone. The study population will consist of individuals living within specified areas of centrifugal spread in the proximity of three pesticide formulating plants in Colorado. The cancer mortality rate for these areas will be compared to that of a similar control population. Cancer mortality data will be collected from death certificate listings for the years 1970 to 1975. Households within the study population will also be interviewed to obtain morbidity data.

EPIDEMIOLOGICAL STUDY OF LEUKEMIA IN MESA COUNTY, COLORADO, U.S.A.

S.W. Ferguson, State Div. of Epidemiology & Disease Control, *4210 E. 11th Ave., Denver, Colorado* 80216

This is a descriptive and analytical study in Mesa County, Colorado, USA, where the age-adjusted leukemia incidence rates are 2-2.5 times the expected, based on Colorado and US data (41 observed: 20 expected in 1970-1976). In the 1950s and 1960s tailings for a uranium mill were used extensively in Mesa County for construction - as a backfill under basements and around foundation walls. For the analytical study the case-control approach is used. Leukemia patients, patients with other malignancies believed associated with ionizing radiation and patients with cardiovascular disease are interviewed. Work over the past year has confirmed the leukemia excess, but has not shown a direct association with residences containing uranium mill tailings.

ANIMAL NEOPLASM REGISTRY - ALAMEDA AND CONTRA COSTA, CALIFORNIA

R. Schneider, University of California, Davis Campus, School of Veterinary Medicine, Dept. of Epidemiology & Preventive Medicine, *Davis, California* 95616

The goal of this project is to help determine the etiology and pathogenesis for as many tumor types and tumor sites as possible by comparing naturally occurring cancers in various species including man. Study of the natural history of cancer in domestic animals and the relationship of cancer in man and animals has been limited because of the lack of adequate animal data. The Animal Neoplasm Registry in Alameda and Contra Costa Counties, California, initiated in July 1963, has developed methods of systematically collecting cancer cases diagnosed by practicing veterinarians. This is the first general animal population-based registry in the world of histopathologically confirmed tumors of all types diagnosed in the animal populations of a defined geographic area. A population-based human tumor registry also functions in the area; thus, human and animal cancer cases are available for comparison. From these data, the following types of studies can be done: (1) characterization of animal cancers such as age-, sex- and breed-specific incidence rates; (2) seeking factors or variables that may affect the risk or occurrence of various cancers in animals and relating them to human cancer occurrence; (3) human-animal association to determine if there is increased human cancer in households where an animal with cancer has lived; (4) human-animal comparisons such as age-and sex-specific incidence rate patterns for clues to possible environmental effects; (5) laboratory studies, e.g. attempts to isolate oncogenic viruses from various tumors or other cancerous animal tissues, and (6) treatment evaluation studies such as evaluation of new treatment methods or approaches prior to application to man.

ESTIMATING THE INCREASES IN SKIN CANCER THAT WILL RESULT FROM INCREASING ULTRAVIOLET RADIATION

E.L. Scott, University of California, Berkeley Campus, School of Letters & Science, Dept. of Statistics, *Berkeley, California* 94720

Increasing ultraviolet radiation (from depletion of the stratospheric ozone or from other causes) will result in increasing skin cancer. The purpose of this study is to estimate the amount of the increase as a function of age, sex, locality, site, skin color, and other characteristics. Efforts are being made to ascertain the influence of microclimate, socioeconomic level, and other factors which may influence the observed increase in skin cancer. Separate studies are made for melanoma, non-melanoma, and keratosis in as much detail as possible; also for mortality, incidence, and prevalence.

EPIDEMIOLOGICAL STUDY OF THE INCIDENCE OF CANCER AS RELATED TO INDUSTRIAL EMISSIONS IN CONTRA COSTA COUNTY

D.F. Austin, State Dept. of Health Services, California Tumor Registry, *2151 Berkeley Way, Berkeley, California* 94704

The study aims (1) to test the hypothesis that the incidence of cancer of specific sites is higher in the population of the heavily industrialized section of Contra Costa County than in the population of the residential areas; (2) to determine whether any union or occupational groups in Contra Costa County have higher incidence rates for any cancer sites than other unions or occupational groups; (3) and to identify specific environmental factors associated with lung cancer incidence in Contra Costa County. Age, race, sex and site specific cancer incidence rates for an 8 year period will be calculated for the group of census tracts in the predominantly industrial section of Contra Costa County and for the remaining group of tracts in the residential section. Rosters of union members and other occupational groups will be matched with cancer incidence files of the Resource for Cancer Epidemiology. The number of cases observed will be compared in the San Francisco-Oakland SMSA. A case-control study of cancer patients in Contra Costa County will be performed. The site, sex and age of the cancer patients will be decided on the basis of the results of the cancer incidence data obtained in the first part of the study. A questionnaire designed to investigate variables, such as length of residence in Contra Costa County, socioeconomic status, smoking, occupation and other causative and contributing variables, will be administered to cases and controls.

HEALTH EFFECTS IN CHILDREN EXPOSED TO VINYL CHLORIDE

R.A. Ziskind, Science Applications Inc., Energy Environment Systems Division, *1801 Ave. of the Stars, Suite 1205, Los Angeles, California* 90067

Although a considerable body of occupational and laboratory toxicological data have demonstrated the carcinogenic action of vinyl chloride monomer (VCM), there appears to be little epidemiological information regarding health effects in children exposed to ambient levels of VCM. A pilot study consisting of a cohort of elementary school children who attended a school situated in close proximity to a PVC manufacturing plant will be conducted for potential health effects 10 to 20 years after exposure. Students will be grouped into three graduated exposure categories based upon estimates of total VCM concentrations received. Plant production history will be linked with pupil records, air monitoring data and dispersion calculations to subgroup the cohort. A number of mortality and morbidity indicators and data bases will be examined in order to contrast all exposure groups with zero exposure population.

RETROSPECTIVE COHORT MORTALITY STUDY OF DRY CLEANING WORKERS EXPOSED TO PERCHLOROETHYLENE

S.D. Kaplan, S R I International, Center for Occupational & Environmental Safety & Health, *333 Ravenswood Ave., Menlo Park, California* 94025

Perchloroethylene is a principal solvent in the dry cleaning industry. This chlorinated hydrocarbon has been shown to cause liver cancer in one strain of mice but not in one strain of rats. The objectives of the study are to identify a population of at least 2,000 individuals in dry cleaning facilities exposed to perchloroethylene as primary solvent and not previously exposed occupationally to either trichloroethylene or carbon tetrachloride who were employed for at least 12 months before 1960, obtain sufficient data to make possible calculation of expected mortality as a function of exposure, carry out follow-up, obtain death certificates and analyze and interpret the results. Eligibles for the cohort have been identified from four union locals, supplemented by solvent histories from sources including: equipment manufacturers and distributors, solvent distributors, and industry representatives. Follow-up will be through the Social Security Administration supplemented as needed by Motor Vehicle Registration and the TelCredit Bureaus. A modified life table analysis will be performed.

EPIDEMIOLOGY OF PANCREATIC CARCINOMA AND IDENTIFICATION OF HIGH-RISK GROUPS

T.M. Mack, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033

The objectives of this research are to study the epidemiology of cancer of the pancreas, to formulate causal hypotheses and to identify groups at high risk of developing this tumor. A large case - control study, to be performed in Los Angeles County, has been designed to permit simultaneous examination of multiple antecedent risk factors. Cases with cancer of the pancreas will be identified by the Los Angeles County University of Southern California Cancer Surveillance Program. questionnaire has been designed to obtain data on occupational and on environmental exposures - tobacco and alcohol consumption, diet, and medical history and treatment. It will be administered to both cases and neighborhood controls as soon as possible after the cases have been diagnosed. Standard matched-pair analyses of multiple variables will be performed on the data from the questionnaire.

MALIGNANT MELANOMA - A CASE-CONTROL STUDY IN LOS ANGELES

T.M. Mack, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033

The annual incidence of malignant melanoma in Los Angeles is about 10 per 100,000 and appears to be increasing. A case-control study has been designed to test and formulate causal hypotheses and to identify groups at high risk. The specific aims of this study are: 1) To quantify the risk of persons for melanoma in relation to job, medical history and particular patterns of behavior, inheritance and skin characteristics, 2) To distinguish between the determinants of risk to different body sites and the determinants of different pathological types. Cases with malignant melanoma will be identified by the Los Angeles County University of Southern California Cancer Surveillance Program. A questionnaire designed to obtain data on occupational and environmental exposures, behavioral patterns in the sun, medical history and treatment, and skin features will be administered to both cases and controls. In addition, skin color will be determined for cases and controls.

EPIDEMIOLOGY OF BENIGN BREAST DISEASE

G.H. Spivey, University of California, Los Angeles Campus, School of Public Health, Dept. of Public Health, *405 Hilgard Ave., Los Angeles, California* 90024

The aim of the study is to examine the epidemiology of major types of benign breast disease and to compare identifiable risk factors for benign diseases with known risk factors for breast cancer. At the same time a histological classification scheme based on grading of cellular atypia in comparison with the conventional histological classification will be examined. Approximately 1,000 women with first biopsies for benign breast disease in participating hospitals will be admitted to the study by a sampling mechanism designed to represent the spectrum of histological types. Histology slides will be reviewed by two independent pathologists and classified on two separate schemes. A group of about 200 women with breast cancer will also be included. Two types of controls will be used, a hospital control and a friend control. Information on epidemiological characteristics will be obtained by questionnaire. The questionnaire seeks responses on a wide range of topics including environmental influences, familial cancer patterns, medical, maturation, and reproductive history, and various other endocrine-related subjects. Epidemiological characteristics of different histological types of benign breast disease will be compared to each other and to those of breast cancer.

EPIDEMIOLOGY OF INTRACRANIAL NEOPLASMS

S. Preston Martin, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033

A large case-control study of two subgroups of patients with primary intracranial neoplasms is to be performed in Los Angeles County: intracranial tumors of all histological types first occurring in children and young people under age 25 from 1972 to 1977; and incident intracranial meningiomas in men from 1972 to 1975. The study has been designed to test the hypothesis that previous radiation exposure is causally related to the development of these tumors, to test previously suggested causal associations, to discover new associations and to delineate the characteristics of the high risk groups. Cases with specified intracranial tumours will be identified by the Los Angeles County-University of Southern California Cancer Surveillance Program. Questionnaires have been designed to obtain data on radiation exposure, occupation, consumption of tobacco and drugs, medical history, and family history of tumors. Standard matched pair analyses of multiple variables will be performed.

3.2311,

A MORBIDITY AND MORTALITY FOLLOW-UP STUDY OF WOMEN TREATED FOR HYPERTHYROIDISM

D.A. Hoffman, U.S. Dept. of Health & Human Services, Public Health Service, Food & Drug Admin., Bureau of Radiological Health, Epidemiology Studies Branch, *5600 Fishers Ln., Rockville, Maryland* 20857

Radioiodine (131I) is now the treatment of choice for persons over the age of 20 years. Although there have been several studies of the possible delayed effects of radioiodine, they have been either too small or have not followed these patients for a long enough time to evaluate adequately the possible carcinogenic effects. The objective of this study is to follow up female patients treated for hyperthyroidism at the Mayo Clinic between 1946 and 1964. This is part of the population that was originally followed up in the National Cooperative Thyrotoxicosis Follow-Up Study. Risks of morbidity and mortality, particularly from malignant neoplasms, will be evaluated. The study will attempt to determine if patients treated with therapeutic doses of 131I are at an increased risk of developing malignant neoplasia compared to patients treated for the same condition with non-radiation modalities. The study design is that of a non-concurrent prospective approach. Eligibility criteria for inclusion in the study cohorts include: 1) treated at the Mayo Clinic for hyperthyroidism between January 1, 1946, and December 31, 1964; 2) a confirmed diagnosis of hyperthyroidism; and 3) United States residency. After review of the Mayo Clinic records, a total of 3,696 white females were ruled eligible for inclusion in the study cohorts. The distribution of patients in the various treatment groups is: 1,004 treated with 131I, 2,141 treated surgically, 426 received both 131I and surgical treatment, and 125 received antithyroid drugs. The medical records of these patients have been abstracted for medical and demographic information. Because the patients were not randomly assigned to the treatment groups, the bases for selection for a particular therapy will be evaluated in order to minimize potential selected biases. Dosimetric information for those patients treated with 131I is being collected in order to estimate various organ doses. Follow-up of these patients is being conducted via mail.

NATIONAL CANCER INSTITUTE PROGRAM OF CANCER SURVEILLANCE, EPIDEMIOLOGY AND END RESULTS (SEER PROGRAM)

J.L. Young, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Biometry Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205

The SEER Program was developed in response to the National Cancer Program requirements for assessing as currently as possible the magnitude of the cancer problem in the United States and for identifying factors related to cancer risk and/or patient survival. The 'cancer problem' has been interpreted to include: 1) newly diagnosed cancer cases that might have been prevented by altering host or environmental conditions and 2) deaths due to cancer that might have been prevented by earlier cancer diagnosis coupled with optimal therapeutic approaches. Therefore, the SEER Program has among its objectives: 1) To assemble and report on a periodic basis, estimates of cancer incidence in the United States. 2) To monitor annual cancer incidence to identify unusual changes in specific forms of cancer occurring in groups defined by parameters of geographical, demographic and social characteristics of the population. 3) To provide continuing information on changes over time in extent of disease at diagnosis, trends in therapy and associated changes in cancer patient survival. 4) To promote the development of hypotheses and specific studies designed to identify cancer aetiological factors (environmental/occupational, sociocultural, etc.) and factors related to patient survival.

3.2314,

EPIDEMIOLOGY OF CANCER AMONG MORMONS

J.E. Enstrom, University of California, Los Angeles Campus, School of Public Health, *405 Hilgard Ave., Los Angeles, California* 90024

The standardized mortality ratio (SMR) for total cancer in 350,000 California Mormons during 1968-1975 and 750,000 Utah Mormons during 1970 -1975 compared with US whites is about 50 percent for 'active' males, about 65 percent for all males, and about 75 percent for all females. For active males the SMR is about 25 percent for smoking-related cancer sites and about 65 percent for all other sites. Mormons are a health-conscious religious group, who appear to be similar to US whites in many respects, such as diet, socio-economic status, and urbanization, but who use substantially less tobacco, alcohol, coffee, and tea than the general population. 'Active' Mormons, and leaders known as High Priests and Seventies, abstain almost entirely from tobacco, alcohol, and caffeine. However, the reasons for the low Mormon cancer rates are largely unknown, primarily because there are no detailed data available on their health characteristics. The objective of this study is to pursue the descriptive mortality data with a questionnaire survey and prospective mortality follow-up of 'active' California Mormon adults, specifically High Priests and their wives. The survey will obtain detailed demographic, life style, dietary, occupational, and medical history data on a representative sample of about 1,000 individuals and limited demographic and life style information on about 20,000 additional persons. Mortality follow-up will be conducted on this cohort for four years. Additional church-based mortality data will be collected for all California Mormons during the years 1960-1967 and 1976-1979 and for all Utah Mormons during 1976-1979, to increase the statistical reliability of the existing data summarized above. The data on life style and health-related characteristics of 'active' California Mormons will be compared with their detailed cancer mortality rates. Distinctive differences between these Mormons and other comparison groups will be highlighted.

REVIEW OF INCIDENCE AND CHANGING PATTERNS OF LIVER TUMORS IN LOS ANGELES

R.L. Peters, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033

As part of an epidemiological study of tumors in Los Angeles County, a broad survey of tumors of the liver is being undertaken. All liver tumors diagnosed at biopsy or autopsy in the County of Los Angeles are microscopically reviewed, terminology and diagnoses are standardized and patient information regarding age, sex, race and previous exposures to potential carcinogens is obtained. Surveys in the past have dealt with death certificate diagnoses only or have accepted submitted diagnoses; this is an attempt to diagnose more precisely the types of tumors to see whether a low incidence tumor, previously buried in the overall designation of 'liver cancer,' is showing a change in incidence.

FOLLOW-UP OF FLUOROSCOPICALLY EXAMINED TUBERCULOSIS PATIENTS IN RELATION TO CANCER INCIDENCE

R.R. Monson, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115

There is current interest in instituting mass screening programs of mammography to detect breast cancer in early stages. However, there is concern that the radiation used may itself have harmful side effects. In this study, the association between radiation received as a result of fluoroscopic examination during air-collapse therapy for tuberculosis and cancer is being assessed. The occurrence of other diseases both in relation to radiation and to isoniazid therapy will also be examined. This is a retrospective cohort study of approximately 9,000 women and men who were treated for tuberculosis in Massachusetts from 1930 onwards. These persons will be followed up from records and other sources. Rates of mortality and cancer morbidity will be compared internally, between radiated and non-radiated patients or between patients treated with and without isoniazid, and externally, with population mortality and cancer morbidity rates.

BLADDER CANCER, LEUKEMIA AND LYMPHOMA AMONG NEW YORK AND WISCONSIN DAIRY FARMERS - A DEATH CERTIFICATE STUDY

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205

A few studies have suggested that dairy farmers have elevated mortality from bladder cancer, leukemia, and lymphoma. To evaluate this lead, 300 deaths from each neoplasm in heavy dairying counties in New York and Wisconsin were individually matched to one control (dying of some other disease) of the same age, race, sex, year of death and county of residence. Type of farming operation for case and control farmers will be determined using records from the State Cooperative Extension Service. The proportions of death certificates listing farmer as the usual occupation and the type of farming operation will be compared in the cases and controls.

IMMUNOLOGICAL AND MOLECULAR HYBRIDIZATION STUDIES OF NASOPHARYNGEAL CARCINOMA

D.V. Ablashi, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Laboratory of Cellular & Molecular Biology, *9000 Rockville Pike, Bethesda, Maryland* 20205 (01823)

EBV is considered a major factor in NPC and the aim is to further assess the role of EBV in terms of etiology, diagnosis/prognosis and other environmental and genetic factors. West Germany and the U.S.A. are low NPC incidence areas. In U.S.A., NPC cases occur in Chinese, whites, blacks and Alaska Eskimos. In Algeria NPC ranks as the number four cancer in males. There are also two age peaks in this population. Since young age NPC has been observed in the black population in some southern states of the USA, Algerian NPC provides an excellent comparison. Examination of approximately 14 cases of German NPC with more than 30 cases from Algeria suggests that antibodies to EBV antigens are much higher in Algerian cases. Data also show that antibodies to EBV, though higher in American than in West German NPC, are not statistically significant. Geometrical mean titers (GMT) of serum antibody to several EBV antigens from 86 cases of NPC from intermediate (Algeria, Tunisia, Malaysia) and from low incidence areas (West Germany and U.S.A.) suggest that VCA-IgA, VCA-IgG and EA-IgG were higher among patients from intermediate risk countires. The only statistically significant difference was for antibody VCA-IgG. Sera tested from 42 NPC patients showed a positive correlation between VCA-IgA and EA-IgA antibodies. NPC biopsies from patients in Algeria were found to contain EBV nuclear antigens, and GMTs of VCA-IgA antibodies from Algerian NPC male patients were higher (36.47) than female (14.69), however only 60 percent of the males were positive to this antigen compared to 82 percent of the females. The correlation between prognosis and high antibody dependent cell cytotoxicity levels was significant. In the series of Algerian patients, most patients were of similar age to those reported in other northern African countries.

3.2323,
EPIDEMIOLOGY OF ACUTE CHILDHOOD LEUKEMIA

M. Szklo, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205

Malignant diseases are the second leading cause of death in U.S. children, with leukemia accounting for about 50% of all childhood cancer deaths. Although a number of factors have been implicated in the etiology of childhood leukemia, including ionizing radiation and chemical agents, the etiology of most childhood leukemias remains unexplained. This case-control study aims to assess environmental influences in childhood leukemia, including factors which may act in utero or in early life. The study population consists of children identified in three metropolitan areas in the U.S. (Baltimore, Philadelphia, and Washington, D.C.). Three groups of about 50 children were individually matched by age, sex, race and hospital of diagnosis: children with acute leukemia, children with other malignancies, and children without malignancies. Interviews have been conducted among parents of these children, and data are now being analyzed.

3.2324,
ENVIRONMENTAL EPIDEMIOLOGY OF PANCREATIC CANCER

L. Gordis, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205

Cancer of the pancreas is the fourth leading cause of death due to cancer in the United States, exceeded by cancer of the lung, colon and rectum, and prostate. This case-control study is designed to investigate environmental factors that may be associated with pancreatic cancer. Cases with pancreatic cancer and two groups of controls -neighborhood controls and hospitalized patients without cancer - and their families will be interviewed. Patients with a diagnosis of pancreatic cancer will be ascertained concurrently from the onset of the study for a period of three years. Cases will be identified from: review of hospital records, pathology records, survey of surgeons and internists, and review of death certificates. Wherever possible, the original slides of biopsy or surgical excision as well as pathology and/or autopsy reports will be obtained and reviewed for verification of diagnosis by a consultant pathologist who will not have the clinical data available to him prior to review of the slides. Patients will be interviewed as soon as is practical after diagnosis, generally during their post-operative convalescence. The spouse or closest relative will also be interviewed. A similar approach will be used for ascertaining information about controls. Data to be obtained in the interviews include: (1) demographic characteristics; (2) past medical history; (3) use of alcohol or tobacco; (4) detailed life-time occupational history; (5) chemical and radiation exposures; and (6) family history of pancreatitis, other digestive diseases, diabetes, or cancer.

3.2325,
RISK OF SECONDARY AMENORRHOEA WITH OR WITHOUT PITUITARY ADENOMA IN RELATION TO ORAL CONTRACEPTIVE EXPOSURE

L. Gordis, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205

The objective of this study is to determine whether women with prolactin-secreting pituitary adenoma and/or secondary amenorrhoea or galactorrhoea have significantly greater frequency or duration of past use of oral contraceptives than controls. The study is a collaborative one, involving Johns Hopkins Hospital, the University of Southern California and the University of California at San Francisco. Study subjects will consist of three case groups and controls. Case groups will consist of women with pituitary adenomas, women without pituitary adenomas who have secondary amenorrhoea and/or galactorrhoea and normal prolactin levels, and women who have no definitive evidence of pituitary adenoma but who have secondary amenorrhoea and/or galactorrhoea and elevated prolactin levels. Neighborhood controls will be selected, and each control will be matched by age and race to a particular case. Data will be obtained from clinical records which will be abstracted for cases only and from interviews which will be conducted with all study subjects. Questions asked during the interview will deal with demographic data, medical, medication, pregnancy, contraceptive, and menstrual histories, possible carcinogenic exposures, and familial medical history.

LUNG CANCER IN LOUISIANA

H. Rothschild, Louisiana State University, Medical Center, School of Medicine, Dept. of Medicine, *1542 Tulane Ave., New Orleans, Louisiana* 70112

Mortality due to cancer of the lung is high in southern Louisiana. Approximately 800 deaths due to cancer of the lung were reported during the seven year (1971-1977) period in ten target parishes (counties). Histopathology has been collected and is being evaluated on almost all deceased persons. Surviving relatives of each person designated as having died of lung cancer are being interviewed concerning the occupation and familial relationships of the deceased. The data on the subjects will be compared with data on controls matched for age, sex, race, and place of residence. Because previous studies have shown a possible relationship between ancestry and cancer, possible familial relationships will be computer analyzed.

MORTALITY AMONG RUBBER WORKERS

R.R. Monson, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115

As part of an on-going study of morbidity and mortality among rubber workers, a cohort of approximately 40,000 employees at one manufacturing plant in Akron, Ohio, is being followed. In this study, the mortality experience according to employees' departments of employment will be examined. The years worked in specific departments, the ages when employed, and the periods of employment in relation to subsequent mortality will be studied. Mortality rates will be compared internally among departments and externally with population mortality rates.

AMERICAN CANCER SOCIETY'S PROSPECTIVE EPIDEMIOLOGICAL STUDY
E.C. Hammond, American Cancer Society Inc., Dept. of Epidemiology & Statistics, *777 3rd Ave., New York, New York* 10017
Large scale prospective studies can provide data that serve as excellent sources for clues to cancer causation in humans. Analyses of mortality from cancer and other diseases from these studies can demonstrate the association of various etiological factors with mortality from different causes. Detailed questionnaires were collected from more than one million men and women representing all population segments by American Cancer Society volunteers who successfully traced almost 99% of the subjects. Copies of death certificates for the deaths were obtained from state health departments whenever a death was reported. Although follow-up ceased in 1972, a small subgroup (approximately 1.5% of the survivors in 1972) is still being traced in 1960. This subgroup is comprised on long-lived subjects (males born prior to 1888; females, 1886). The object of this study is to elucidate those factors associated with cancer prevention.

RISK OF BREAST CANCER IN WOMEN WITH BENIGN BREAST LESIONS USING ORAL CONTRACEPTIVES
S. Graham, State University of New York, Buffalo Campus, School of Social Science & Admin., Dept. of Sociology/Social & Preventive Medicine, *3435 Main St., Buffalo, New York* 14214
At least one investigator has found a higher risk of breast cancer in women using oral contraceptives who have a history of benign breast lesions. Arrangements have been made with Dr. Takuma Nemoto to administer a simple two-page questionnaire to women with breast cancer at the Roswell Park Memorial Institute. Age-matched controls are selected from the Dermatology and Thoracic service at the Roswell Park Memorial Institute. It is anticipated that approximately 300 breast cancer patients can be surveyed per year at the Institute. The questionnaire administered contains questions dealing with the major hypotheses of breast cancer etiology, including parity, age at first pregnancy, lactation, and the like, as well as questions dealing with use of the various oral contraceptives and a history of past benign breast lesions. Information pertaining to use of the pill and history of past benign breast disease is corroborated through medical records. To data, 224 case and 130 control questionnaires are complete.

COMPARATIVE STUDY OF BLADDER CANCER IN THE U.S. AND EGYPT WITH EMPHASIS ON THE ROLE OF SCHISTOSOMIASIS IN CAUSATION OF BLADDER CANCER IN EGYPT
G.M. Sayed, University of Nebraska, Medical Center, School of Medicine, Dept. of Epidemiology, *42nd & Dewey Aves., Omaha, Nebraska* 68105
Cancer of the urinary bladder is one of the few malignant neoplasms in which the role of environmental factors has been determined. At least four of every five cancers in man have their origin in the environment. Bilharziasis is an endemic parasitic disease in Egypt, and affects 40% of all the country's farmers in their third decade of life. Bladder cancer constitutes 28% of all malignant tumors in Egypt. Data were collected from the Ministry of Health in Cairo, Egypt, The Egyptian National Cancer Institute, Cairo, the Department of Urology in Egyptian General and University Hospitals, the Department of Endemic Disease Control, State Health Department and Preventive Medicine and Biostatistics Departments in three Colleges of Medicine, Cairo, Egypt. The incidence of this form of cancer in the western hemisphere and in industries is compared with that in Egypt. Also, case-control studies for Egypt and the U.S. are compared. Histopathological patterns in both sectors will be studied in an effort to find an area of commonality between the types of environmental, social and cultural factors and the patterns of bladder cancer.

HISTOLOGICAL FINDINGS IN BRONCHIAL EPITHELIUM IN RECENT AUTOPSIES
O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Senior Medical Investigator's Laboratory, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019
During the past two decades tar and nicotine content of American cigarettes have been greatly reduced. Although lung cancer death rates have continued to rise, evidence from recent epidemiological studies shows that mortality rates have now started to decrease. If reduction of tar and nicotine reduces the risk of lung cancer, then the degree of histological changes in the tracheobronchial tree of men who were autopsied in recent years would be less than in men who died 15 or more years ago. A total of 182 cases collected between 1955-1960 were matched with 182 cases who died between 1970-1977. Cases were matched on age and smoking habits. These records were supplemented by 29 additional 1955-1960 cases and 52 cases from 1970-1977. 55 slides were prepared for each case, a total of 20,424 slides. After the cases were selected, the slides were placed in random order and identified only by a serial number. The findings on number of cell rows, percent with atypical nuclei, carcinoma in-situ and early invasive cancer were recorded on code sheets and later key punched and combined by cases for analysis. Results were published in the N.Engl.J.Med. 300, 381-386, 1979. In both periods the histological changes increased with the amount of cigarettes smoked. Sections with advanced histological changes (carcinoma in-situ) occurred far more frequently in smokers who died in 1955-1960. Since all of these subjects smoked cigarettes higher in tar and nicotine up to the time of death than those smokers who died in 1970-1977, the differences in findings can be attributed to the changes in tar and nicotine content of the cigarette smoked. The study continues.

HISTOLOGICAL CLASSIFICATION OF LUNG CANCER IN PERSONS EXPOSED TO ASBESTOS
O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Senior Medical Investigators Laboratory, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019
Studies of uranium miners who died of lung cancer have shown a different pattern of histological types from that in non-miners who die of lung cancer. Although there have been some studies of histological type of lung cancer in asbestos workers, these have been on a small series and not classified by the WHO classification of tumor type. Tissue specimens of lung cancer cases (autopsy and surgical specimens) on all subjects diagnosed with lung cancer in a 13 year period are being collected. Asbestos-exposed and non asbestos-exposed persons will be included in this study. Smoking, occupational and residence histories will be obtained from families of the decreased.

3.2337,
RELATIONSHIP BETWEEN CANCER MORTALITY AND ENVIRONMENTAL FACTORS
P.W. Preuss, State Dept. of Environmental Protection, *P.O. Box 1390, Trenton, New Jersey* 08625
The proposed project will correlate the geographical patterns of cancer mortality with environmental and industrial data in the following manner: (1) Statewide environmental and industrial data will be collected for as far back in time as the sources permit. (2) A list of approximately 600 environmental and industrial variables will be identified to be correlates to the cancer mortality data. (3) These variables will be correlated to the cancer mortality data. The mathematical techniques will include bivariate correlation and factor analysis. Bivariate correlation is a statistical tool for measuring the relationship between two variables. Factor analysis provides a measure of the extent to which groups of different variables correlated. Through the use of these techniques, both individual factors and groups of factors which correlated with cancer mortality will be identified. (4) From these results of the correlation of the 600 variables, a list of those 20 to 40 which correlate most strongly with cancer mortality will be generated. (5) Intensive data searches will be conducted in order to reconstruct a 30 year period of population exposure to the 20 to 40 selected variables. (6) Annual exposure rates will then be correlated to annual mortality data to determine if relationships exist between exposure and mortality. In performing these correlations the 20-30 year latency period for cancer will be considered. (7) A final report will be prepared explaining all findings and recommending future courses of action.

FAMILIAL STUDIES OF CANCER

S. Albert, Michigan Cancer Foundation, Dept. of Biometry & Medical Sociology, *110 E. Warren Ave., Detroit, Michigan* 48201

A retrospective study of cancer incidence among family members. associations between different forms of cancer and other characteristics of cancer lineages is being conducted. The study group consists of more than 6,000 families of post-partum women who participated in studies of viral-like particles in human milk from 1971-1977. Extensive family histories were obtained from these women in the effort to establish a relationship of the presence of viral-like particles to a family history of cancer. These data have been a valuable resource for epidemiological investigation and are central to several studies.

INVESTIGATION OF HIGH PANCREATIC CANCER RATE IN WESTERN NEBRASKA

E. Mahboubi, University of Nebraska, Medical Center, School of Medicine, Dept. of Epidemiology, *42nd & Dewey Aves., Omaha, Nebraska* 68105

Seventeen cases of pancreatic cancer were diagnosed in less than one year in the newly staffed Western Nebraska General Hospital of Scottsbluff, Nebraska. The unit serves a population of approximately 60,000 inhabitants. The number of cases constitutes an incidence four times greater than expected. This situation prompted the setting up of a survey to (1) confirm the high occurrence of pancreatic cases, (2) study places of birth and residence of cases for the purpose of establishing incidence rates, (3) establish a retrospective case-control study to look for common environmental or cultural factors prevalent among the cases which might be associated with the occurrence of pancreatic cancer in the area, (4) determine any possible risk factors such as occupational exposure to known carcinogens or any factor suspected to be associated with the cases. There will be at least two controls for each case. Eleven Western Nebraska counties, Scottsbluff, Sioux, Dawes, Sheridan, Box, Banner, Morril, Garden, Kimball, Cheyenne and Deuel, with a population of 95,000, are included in the study.

THE NURSES HEALTH STUDY

F.E. Speizer, Harvard University, Boston Campus, School of Medicine, Dept. of Medicine, *25 Shattuck St., Boston, Massachusetts* 02115

The risks of various possible carcinogenic exposure in women have not been well described. This prospective cohort study aims to evaluate cancer morbidity and mortality for a number of exposures including oral contraceptive use, cigarette smoking, use of a variety of dietary nutrients, and hair dyes. Information has been obtained by mail by questionnaire for 121,964 married, female registered nurses, residing in one of 11 larger US states, and listed in the directory of the American Nurses' Association in 1972. Biannual follow-up mailings are being performed in 1978 and 1980 to determine the incidence rates of various cancers in relation to the exposures under investigation. Particular emphasis is placed on risk factors for the development of breast cancer. The information base for 1980 will be expanded to include detailed assessment to provide baseline data for follow-up investigation of outcome for 1982.

OCCUPATIONAL, ENVIRONMENTAL, AND PERSONAL-HABIT-RELATED DISEASES IN THE GREATER WORCESTER AREA

B.S. Levy, University of Massachusetts, Medical School at Worcester, School of Medicine, Dept. of Family & Community Medicine, *55 Lake Ave. N., Worcester, Massachusetts* 01605

There is increasing evidence that much cancer results from occupational exposures. This case-control interview study aims to identify occupational and other factors related to the development of leukemia and cancers of the lung, urinary bladder, kidney, and larynx. Approximately 300 cancer patients who meet the study criteria are being identified from the cancer registries of the five major hospitals in Worcester, Massachusetts. These criteria include a tissue diagnosis of one of the malignancies under study at one of these hospitals in 1976 or 1977 in patients aged 21 years or older who live in Worcester or one of the immediately adjacent towns. After consent is obtained, these patients are interviewed (or their next of kin, if they are deceased) concerning their occupational, residential, and smoking histories; non-occupational exposures to possibly hazardous substances; family history of cancer; long-term use of medications; and ingestion of coffee and alcohol. An equal number of control subjects are being interviewed. The control subjects are patients at the same hospitals in the same years without a history of any malignancy who have been matched to cancer patients in the study by sex and five year age-group and who live in the same residential area. While the total number of cancer patients and control subjects is relatively small, it is hoped that this study may yield clues for investigation by more specific cohort studies of workers of the same occupation, in the same industry, or with the same exposure.

HERPESVIRUS HOMINIS TYPE 2 ANTIBODIES IN RELATION TO THE DEVELOPMENT OF CERVICAL NEOPLASIA

L. Johnson, New England Regional Primate Research Center, *1 Pine Hill Dr., Southborough, Massachusetts* 01772

An assay of herpesvirus hominis type 2 hemagglutinating antibodies is being made in sera of patients, before the onset of disease, during stages of cervical neoplasia and after treatment and compared with sera of controls who did not develop cancer. This prospective study is possible because sera were collected at the Boston Hospital for Women from pregnant and postpartum women during the years 1959-1965 in the Collaborative Study of Cerebral Palsy. These same women had Papanicolaou smears taken during the same time period in a study of the histogenesis of cervical neoplasia. A sample group of the women was re-examined for cervical neoplasia and serum was collected during the years 1974-1977.

EVALUATION OF PERIODIC BREAST CANCER SCREENING WITH MAMMOGRAPHY AND CLINICAL EXAMINATION

W. Venet, Health Insurance Plan of Greater New York, Dept. of Research & Statistics, *625 Madison Ave., New York, New York* 10022

This is a randomized trial designed to test whether periodic screening with clinical and mammographic examinations results in a long-term reduction in breast cancer mortality. Linked to this primary objective are several issues of major importance in assessing benefits to be derived from breast cancer screening, e.g., the relative value of the two screening modalities, ages of women to be screened, periodicity of screening, identification of parameters related to development of the disease, and determinations of underlying cause of death. Approximately 62,000 women, aged 40-64 at the time of entry to the study and allocated to either a study or a control group, are under surveillance. Study women were offered screening examinations; of the 65 percent who accepted an initial examination, a large majority had at least one of the three additional screenings at annual intervals. Control women continued to receive their regular medical care. Screening ended in mid-1970, and follow-up on the entire study and control populations for breast cancer cases and death ascertainment continues. The survival status of all known breast cases through December of 1977 has been established, and no one is lost to follow-up. New data support earlier results on screening benefits. At ten years of follow-up from entry, 30 percent differential exists between the total study (screenees and refusers) and control group in breast cancer mortality. The impact of the screening program continues to be confined to women 50 years of age and over with no benefit at ages 40-49. Eight-year case fatality rates show similar relationships. The differential between control and study cases is due almost entirely to the low rates among cases detected through screening, with cases detected through mammography alone showing a rate that is exceptionally low. At this point in the study there appears to be strong support for periodic screening at ages of 50 years and over with the two modalities.

MORTALITY OF WORKERS EXPOSED TO POLYCHLORINATED BIPHENYLS IN MANUFACTURE OF TRANSFORMERS AND CAPACITORS

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *1 Gustave L. Levy Pl., New York, New York* 10029

The entire workforce employed 1952-1957 in the largest U.S. facility manufacturing capacitors and transformers has been identified with assistance of the plant's union and management. The plant's operation goes back to 1947 and much information is available concerning polychlorinated biphenyl (PBC) exposure, including the types of PBC used over the years. Estimates are also available concerning the intensity of exposure in the various work positions. Age-, year-, and sex-specific deaths will be calculated for this large cohort, on the basis of both state and local death rate data, as well as data of the U.S. National Office of Vital Statistics. The entire cohort is being traced and the observed deaths will be compared with those estimated. While the duration from onset of exposure is shorter than optimal (being only 25 years in some cases), the information to be obtained will at least give data concerning the short-term mortality experience of a group heavily exposed to this halogenated hydrocarbon.

MORTALITY AMONG AMOSITE ASBESTOS FACTORY WORKERS IN RELATION TO SMOKING HABITS, 1961-1977

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *1 Gustave L. Levy Pl., New York, New York* 10029

The mortality experience of workers in an amosite asbestos products factory is being reviewed prospectively from 1 July 1961, according to individually ascertained smoking habits. Deaths to 31 December 1977 have been recorded and causes of death, including cancer by specific site, asbestosis and other non-infectious lung disease, ascertained. Calculations include expected and observed deaths for those with a history of cigarette smoking and those who have smoked pipe and/or cigar only. Expected deaths are calculated according to age, year and sex specific death rates for the State of New Jersey, first by cause and then separately calculated in smoking specific categories, utilizing death rates over much of the period in question for similar men in a prospective study, by smoking category, of the American Cancer Society. During the period 1 July 1961-31 December 1977, 311 deaths occurred, including 62 from lung cancer. Observation of the cohort survivors continues.

MORTALITY EXPERIENCE OF SHIP REPAIR WORKERS

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *1 Gustave L. Levy Pl., New York, New York* 10029

Although it is unlikely that there will be wide use of asbestos in new ship construction in the United States in the future, asbestos already in place in many U.S. and foreign ships promises to pose a hazard as these vessels are submitted for repair, maintenance, modernization and renovation. A cohort of all workers is being established in a major eastern U.S. shipyard which has been engaged entirely in ship repair and maintenance since the late 1930s, including all men and women so employed at some time between 1954 and 1964, for at least five years. The status of these individuals will be ascertained as of January 1, 1979. Cohort members will be categorized by trade and for those who have died, causes of death ascertained. A large proportion of the survivors in 1979 will be clinically examined for stigmata of asbestos-associated disease.

Description provided by IARC and DKFZ with ICRDB/NCI support.

METABOLIC EPIDEMIOLOGY OF COLON CANCER AND BREAST CANCER

E.L. Wynder, American Health Foundation Inc., Dept. of Epidemiology, *320 E. 43rd St., New York, New York* 10017

The primary objective of this investigation is to study the epidemiology of colon cancer cases and controls in a high-risk population (Finland) and a medium-risk population (US), paying special attention to the effect of diet on fecal constituents, and to study the constituents in breast fluid from those population groups. It is planned to continue collecting samples from populations at different risks for col n and breast cancer and analyze them for fecal constituents, hormones, mutagens, and/or other components. Results will be correlated epidemiologically to determine dietary or other associations with population differences.

Description provided by IARC and DKFZ with ICRDB/NCI support.

3.2352,

METABOLIC EPIDEMIOLOGY OF COLON CANCER - STUDIES IN LOW RISK FINNISH POPULATION

B.S. Reddy, American Health Foundation Inc., Division of Nutrition, *Hammond House Rd., Valhalla, New York* 10595

Colon cancer incidence data from the Nordic countries show a gradient from rural areas in Northern Finland, increasing from Northern to southern Sweden, with highest incidence being reached in Copenhagen, Denmark. Studies thus far completed indicate that excess dietary fat exerts an effect by altering endogenously produced metabolites such as bile acids which appear to have a promoting effect in colon cancer incidence and that dietary fiber has a protective effect in colon carcinogenesis. Although the total dietary fat intake in rural Kuopio, Finland is similar to countries with a high rate of colon cancer, the crucial difference in dietary intake between Kuopio and USA may relate to dietary fiber. The overall objective of this study is to acquire significant information in the high and low risk populations for development of colon cancer on the role played by dietary components on the etiology of this disease. In order to achieve this objective, feces of healthy controls and patients with colon cancer in Kuopio and Helsinki, Finland, and New York Metropolitan area will be analyzed for bile acids, beta-glucuronidase, 7-alpha-dehydroxylase and mutagens. Dietary intake of fiber and fecal bulk will also be determined in these populations.

Description provided by IARC and DKFZ with ICRDB/NCI support.

SUPPORTED BY (No Supporting Organization Reported) funds n.a.

3.2353,

ROLE OF DIETARY FACTORS IN CANCER OF THE INTESTINAL TRACT

E.L. Wynder, American Health Foundation Inc., Dept. of Epidemiology, *320 E. 43rd St., New York, New York* 10017

The primary objective is to study the epidemiology of gastrointestinal cancers in a high-risk country for gastric cancer (Yugoslavia) and in a low-risk country (United States). A case-control study will be used to determine whether a diet high in cereals and starches and low in fresh vegetables may be linked to gastric cancer. The study will be conducted in three geographical regions: two areas in Yugoslavia, where a strong intra-country gradient exists, i.e., Panonia (high-risk) and Karst (medium-risk), and New York City. It is also intended to determine whether a diet high in fat and low in fiber may be linked to cancer of the colon, as determined by dietary history in a case-control study. The study is to be conducted in the same three geographical areas. The data will be examined to discover whether any epidemiological differences exist between diffuse and intestinal types of gastric cancer. The association between beer consumption and cancer of the rectum will be tested. Data for this case-control epidemiological study are collected by trained research interviewers and more than 500 cases and 600 controls have been interviewed in the American phase of the study. Data collection will begin in Yugoslavia in late 1979.

3.2354,

METABOLIC EPIDEMIOLOGY OF COLON CANCER

B.S. Reddy, American Health Foundation Inc., Division of Nutrition, *Hammond House Rd., Valhalla, New York* 10595

The distribution of cancer of the colon, particularly its infrequency in Japan, its increase among Japanese immigrants to the United States and the high rate of this disease among North Americans and most Western Europeans, strongly indicates that a dietary factor, mainly high fat and animal protein, is of etiological significance. Preliminary studies in metabolic epidemiology have shown that the dietary composition and intestinal microflora play a significant role in the composition of intraluminal compounds such as cholesterol metabolites and bile acids which can act as co-carcinogens for the colon. The overall objective of the proposed research is to delineate the relationship among dietary components, intraluminal compounds, intestinal microflora and colon cancer in man, and to develop a biochemical and/or a bacterial indicator for colon cancer. In order to elucidate the etiological role of bacterially modified intraluminal compounds on the incidence of colon cancer, feces of high risk and low risk populations, patients with colon cancer, polyps, familial polyposis and ulcerative colitis will be analyzed for cholesterol metabolites, bile acids, tryptophan metabolites, microflora and bacterial beta-glucuronidase and 7-alpha-dehydroxylase activities. From these studies, we wish to develop a biochemical and/or a bacterial indicator which distinguishes low and high risk populations for large bowel cancer.

DATA BANK FOR STUDY OF THE EPIDEMIOLOGY OF CHILDHOOD CANCER

S. Grufferman, Duke University, School of Medicine, Comprehensive Cancer Center, *Box 3711, Durham, North Carolina* 27710

The major objective of this study is to learn more about the epidemiology of childhood cancers. A questionnaire will be administered to the parents of all childhood cancer patients seen at the Duke Medical Center and to matched hospital controls with information banked for later case-control studies. The epidemiologic data collected will be used to study the descriptive epidemiology of various childhood tumors (singly and in various groupings) as well as associations with potential antenatal, childhood, familial, and environmental etiologic exposures. Information modules on nutrition and radiographic findings are to be added in the near future.

ASSESSMENT OF PAST DIET IN CANCER EPIDEMIOLOGY

M.A. Ibrahim, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514

The need for a reliable method of estimating dietary consumption in the past has become critical in case-control epidemiologic studies on the relationship of diet to cancer. The research objective of this study is to estimate the reliability and validity of estimates of past dietary intake which are derived from present diet histories or from retrospective diet histories. A population on which a current diet history was obtained in 1963 is located in Evans County, Georgia. This population is being reinterviewed for their recollections of their diet in 1963, and their current diet in 1977. The validity of the retrospective diet history will be assessed by comparing it to the diet history obtained in 1963. The degree of dietary change in this population in 14 years will be assessed by comparing the 1977 current diet history to the 1963 history. Comparisons will be made of average consumption of specific food items. Correlation coefficients of individual consumptions as reported on the respective surveys will also be calculated. This study will establish quantitative estimates of the validity and reliability of obtaining dietary history, retrospectively. Should these estimates prove low, waste of resources on unreliable studies will be avoided. Should they prove high, studies will not fail to be undertaken because of negative criticism of these methods.

PILOT STUDIES OF ENVIRONMENTAL FACTORS AND CANCER MORTALITY

G.S. Wilkinson, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Population Studies Div., *Research Triangle Park, North Carolina* 27709

These studies are concerned with investigating potential relationships between environmental factors such as presence of asbestos mines or proximity of nuclear and fossil-fueled power plants and mortality from cancer within the United States. Mortality rates for various types of cancer in areas having asbestos mines or power plants are being compared with mortality rates in areas without such sources of potential pollution.

PILOT STUDY OF AMBIENT AIR POLLUTION AND SURVIVAL OF CANCER

G.S. Wilkinson, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Population Studies Div., *Research Triangle Park, North Carolina* 27709

This study is concerned with analyzing potential relationships between reported levels of air pollution in the ambient air and length of survival for diagnosed cancer patients. Categorical indicators of pollution levels will be derived from data available from the National Aerometric Data Bank. Survival times for patients having histologically confirmed cases of cancer who have been accessioned into the Lakes Area Regional Tumor Registry will be analyzed by life table and other appropriate methods. This investigation will permit preliminary statements about the effect that various concentrations of ambient air pollutants may have upon the length of survival of patients having a serious chronic disease - cancer.

STUDY OF WORKERS IN A SODERBERG ALUMINUM SMELTER

C.R. Buncher, University of Cincinnati, College of Medicine, Dept. of Epidemiology & Biostatistics, *Eden & Bethesda Aves., Cincinnati, Ohio* 45221

Several recent studies have suggested that workers in aluminum smelting are subject to an excess risk of lung cancer and some types of leukemia and lymphoma. The indications are that pot room workers are most subject to the risk. This study of 2,700 workers is a follow-up of previous reports with the purpose of trying to relate specific work assignments in this plant with possible excess cancer risk in an occupational mortality study. Death certificates are being obtained and will be compared by work classification within each department of the production facility. This study is part of a tri-partite research project involving industry, labor unions, and government.

MORTALITY EXPERIENCE AMONG A COHORT OF CADMIUM SMELTER WORKERS

R.A. Lemen, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Animal and human studies have shown increased risks of malignant and non-malignant disease from exposure to cadmium. Specifically NIOSH cohort mortality studies have shown increased risks of prostatic and respiratory cancer among a cohort of cadmium smelter workers having been exposed for two years or more in the smelter. Employment records to identify all workers in the facility are coded and follow-up has been initiated to determine vital status of the remaining approximately 1,300 individuals who have ever worked in the smelter. Pathological and medical histories still remain to be collected concerning those deaths which have been identified so far.

MORBIDITY AND MORTALITY PATTERNS AMONG OCCUPATIONALLY EXPOSED ASBESTOS WORKERS (ABBREV)

R.A. Lemen, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Considerable controversy has arisen concerning the validity of true exposure to chrysotile asbestos and its relative importance in the etiology of mesothelioma. Animal experimental evidence is contradictory. One study indicates that Canadian and Rhodesian chrysotile asbestos is the least carcinogenic fiber for mesothelioma, while another study has shown no fiber difference. This investigation will evaluate the risk of mesothelioma from exposure to chrysotile asbestos. It will also evaluate the usefulness of cross-sectional medical data perimeters as indicators of future asbestos-associated disease, e.g., lung cancer, mesotheliomas, gastrointestinal cancer, etc. A prospective analysis of tobacco usage (smoking of cigarettes, pipes, cigars and tobacco chewing) obtained through cross-sectional medical studies will be evaluated in those workers known to have died as a result of lung cancer, mesothelioma and gastrointestinal cancer.

EPIDEMIOLOGY OF CANCER OF THE PENIS

L. Persky, Case Western Reserve University, School of Medicine, Dept. of Urology, *2109 Adelbert Rd., Cleveland, Ohio* 44106

Cancer of the penis will be studied in relation to recurrent antecedent surgery and other local irritative factors such as trauma of various sorts, exposure to various synthetic materials and previous infection. Any regional occurrence of cancer will be compared to that of cancer of the penis and the incidence of cancer of the penis will be surveyed for the past year to see if there has been an increasing or decreasing incidence or whether its occurrence is static. Local regional factors, such as industrial toxins, fumes, organic chemical usage and the like will be studied also to see if any relationship between these substances and cancer of the penis can be found.

LONG-TERM STUDY OF MINERS EXPOSED TO RADON-222

E.P. Radford, University of Pittsburgh, Graduate School of Public Health, Dept. of Epidemiology, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260

Eight 5-year cohorts of underground miners born 1880-1919, who are still living or have died in Malmberget, Sweden, have been followed up to 1976. Exposure doses are calculated from radon-daughter measurements in air and water and from radioactivity in water springs in the mines measured in 1914. Attention has been paid to the different depths of the mine over the years and ventilation in different places of work. substantial number of lung cancer cases have occurred in miners who never smoked or were ex-smokers. A survey of smoking prevalence in active and retired miners has been done to permit assessment of the role of smoking in relation to radon-daughter exposures in the genesis of bronchial cancer. Follow-up of all 1,441 miners is now complete and the data are being analysed.

ANALYSIS OF MORTALITY PATTERNS IN ALUMINUM REDUCTION PLANTS

H.E. Rockette, University of Pittsburgh, Graduate School of Public Health, Dept. of Biostatistics, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260

A review of the literature on the health effects of worker exposures in the reduction of aluminum indicates that there may be an excessive incidence of respiratory cancers among workers exposed to high levels of coal pitch volatiles. Furthermore, there may be an excessive incidence of other cancers and of chronic obstructive respiratory disease. The largest study to date was a historical prospective study sponsored by the Aluminum Association. In that study, 23,033 men employed for five years or more during the period 1941-1973 at one of fifteen aluminum reduction plants in the United States were followed up through 1973. The present study will use these records as a data base. The objectives of the new study are as follows: (1) to verify the accuracy of the initial data collection, (2) to obtain job histories and include these in the analysis, (3) to obtain estimates of exposure levels, and (4) to extend the follow-up period through 1977. Mortality patterns of groups of workers with varying levels of exposure and of general populations will be compared.

DYSPLASIA OF GASTRIC MUCOSA

S.C. Ming, Temple University, School of Medicine, Dept. of Pathology, *3322 Broad St., Philadelphia, Pennsylvania* 19122 (01420)

The objectives of this project are two-fold: (1) Establishment of criteria for grading of gastric dysplasia, and (2) Study of prevalence of gastric dysplasia in different countries. It has long been recognized that certain conditions in the stomach are pre-cancerous. Among them are pernicious anemia, chronic atrophic gastritis, intestinal metaplasia, adenoma, and chronic ulcer. The common anatomical basis for increased cancer incidence in patients with these conditions is dysplasia of the epithelial cells. Study of prevalence of dysplasia is, therefore, important. In spite of this recognition, however, there is the need to establish uniform criteria for making the diagnosis. For this reason the International Study Group on Gastric Cancer has directed members of its pathology panel

to establish the criteria. This assignment is in the process of being carried out. Once the criteria are established, they will be used by the group to determine prevalence rate of different grades of gastric dysplasia and to correlate the information with prevalence rates of gastric cancer.

EPIDEMIOLOGY OF CHILDHOOD CANCER

S.L. George, St. Jude Childrens Research Hospital, Biostatistics Section, *332 N. Lauderdale St., P.O. Box 318, Memphis, Tennessee* 38101

This general study will attempt systematic gathering of data from all children with malignant disease admitted to a large children's research hospital. The overall objectives are to characterize better the features of children with cancer and their families and to search for clues to etiology. Techniques to be used include the following: retrospective review of medical records; questionnaire/interview of families at diagnosis when possible; follow-up interviews and examinations for late effects, up-dates of initial information and progeny of long-term survivors; case-control studies where feasible. Over 300 newly diagnosed patients with cancer are admitted each year, mostly from the immediately surrounding, largely rural area. Areas to be systematically covered for all families include: socio-economic/occupational history, exposure to known carcinogens/pathogens (including ionizing radiation), previous diseases, other environmental factors and host factors (familial cancer, congenital abnormalities, etc.). An initial case-control study of children with colorectal cancer, using neighborhood controls, has begun.

EPIDEMIOLOGY OF PRIMARY LIVER CANCER IN SELECTED COUNTIES OF TEXAS

P.A. Buffler, University of Texas, Medical Branch at Galveston, School of Medicine, Dept. of Preventive Medicine & Community Health, *300 University Blvd., Galveston, Texas* 77550

Several counties in Texas have been identified as having high rates of primary liver cancer (PLC), approximately three times as great as that reported for the total U.S. Three of these 'high rate' counties are associated with heavy chemical and petrochemical industry concentrations. In 1977 a retrospective study of all liver cancer deaths occurring in Brazoria County, Texas, during the interval 1960-75 was conducted to determine if the proportion of chemical workers is higher among persons dying from primary liver cancer than among persons dying from non-malignant diseases. Occupational histories were obtained from participating industries for all cancer deaths and controls. Clinical and histopathologic review of all deaths due to PLC and other liver-related diseases is being conducted. The study is currently being extended to the two larger counties, Orange and Jefferson, which also have a heavy concentration of chemical and petrochemical plants. Additional studies are anticipated in Texas counties having high rates of PLC which are nonindustrialized but where exposure to hepatitis B, insecticides or aflatoxin B may be involved.

INCIDENCE, MORBIDITY AND NATURAL HISTORY OF CANCER IN THREE ETHNIC GROUPS IN TEXAS (ABBREV)

E.J. MacDonald, University of Texas, University of Texas System Cancer Center, M.D. Anderson Hospital & Tumor Inst., Dept. of Epidemiology, *6723 Bertner Ave., c/o Texas Medical Ctr., Houston, Texas* 77030

The objective is to study incidence and natural history of and differences in various types of cancer by ethnic group (white except Spanish surnamed; non-white and Spanish surnamed individuals) and geographical area at the community level hospital and specialized cancer hospital. Metastases for a 30-year period (35,000 patients with 100,000 metastatic sites) will be analyzed, as well as multiple primary cancer. Age-adjusted incidence rates (1944-1966) have been computed for six regions in Texas for three ethnic groups.

IMPACT OF CANCER ON TEXAS - AN EPIDEMIOLOGICAL ANALYSIS

V.F. Guinee, University of Texas, University of Texas System Cancer Center, M.D. Anderson Hospital & Tumor Inst., Dept. of Epidemiology, *6723 Bertner Ave., c/o Texas Medical Ctr., Houston, Texas* 77030

In the first phase of the analysis, descriptive epidemiological studies are being based on cancer mortality (1969-76) as reported to the State on death certificates and county population data from the 1970 census. Age-adjusted rates for each county and Health Services Areas have been calculated. Total cancer mortality and the mortality from ten major cancer sites have been detailed in a publication 'Impact of Cancer on Texas'. Future analyses will include geographical and ethnic patterns, as well as in-depth studies of populations with apparent high and low risks of developing cancer. New mortality data will be incorporated in the computerized data base as they become available.

RELATIONSHIP OF FECAL NEUTRAL STEROIDS TO LARGE BOWEL CANCER RISK

T.D. Wilkins, Virginia Polytechnic Inst. & State University, Anaerobic Bacteriology Lab., *P.O. Box 49, Blacksburg, Virginia* 24061 (01510)

The objectives of this study are to analyze excretion patterns of long chain fatty acids and neutral steroids in populations at known risk for colon cancer, to analyze for fecal mutagens in these populations, and to determine if patterns of excretion of fecal neutral steroids or long chain fatty acids correlate with fecal mutagen production. Degradation of cholesterol in the colons of populations at low risk and high risk for colon cancer will be measured and concentrations of oleic acid and neutral steroids in the feces of populations at different risk levels will be compared. Fecal samples from South Africa, Scandinavia and the United States will also be extracted with ether and the extracts tested for mutagenicity using the Salmonella mutagenicity test of Ames. To date it has been noted that excretion of mutagens was higher in a population at high risk for colon cancer than in two populations of low risk (Ehrich et al, Mutat. Res. 64. 231-240, 1979). At present it also appears that low fiber diet or genetic predisposition to colon cancer (patients with familial polyposis) did not result in an increased frequency of excretion of fecal mutagens.

REGISTRY FOR CARCINOMA IN SITU OF THE VULVA

E. Wilkinson, Medical College of Wisconsin, School of Medicine, Dept. of Gynecology & Obstetrics, *561 N. 15th St., Milwaukee, Wisconsin* 53233

The registry operates under the auspices of the International Society for Study of Vulvar Disease. In accordance with the new nomenclature, this includes cases of squamous cell carcinoma in situ (formerly Bowen's disease, erythroplasia of Queyrat and carcinoma simplex) as well as cases of vulvar Paget's disease. The purpose of the Registry is to accumulate epidemiological and histological data in order to define the biological characteristics of the disease, determine its frequency and identify the high risk patient. Histological slides and completed registry forms are kept in a central file and the data are compiled at regular intervals. Over 100 cases have been collected since the Registry opened. Physicians desiring to register cases or obtain additional information are asked to contact Dr. Peter J. Lynch, Professor or Dermatology, University of Arizona Medical Center, Tucson, AZ 85724, or Dr. Raymond H. Kaufmann, Professor and Chairman, Baylor College of Medicine, Texas Medical Center, Houston, TX 77025.

EPIDEMIOLOGICAL STUDIES OF CANCER

J.F. Fraumeni, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Environmental Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205

The Environmental Epidemiology Branch of the National Cancer Institute of the United States conducts and coordinates a variety of studies in cancer epidemiology. Some of these are outlined below. (1) Following a county-by-county mapping of cancer mortality, several correlation and analytical studies are underway to help identify the environmental determinants of cancer in high-risk communities. (2) A program of occupational studies searches for cancer hazards associated with various industries, for example, petrochemicals, pharmaceuticals, printing, leather, dry-cleaning, automobile, pest control and metal smelters. (3) The carcinogenic effects of drugs are evaluated by studies of cancer risk following use of exogenous estrogens, alkylating agents, and immunosuppressive therapy. (4) Evaluation of radiation-induced cancer involves surveys of women receiving repeated chest fluoroscopy for tuberculosis, survivors of the atomic bomb, and recipients of radioactive iodine for diagnostic or therapeutic reasons. (5) Mechanisms of host susceptibility to cancer are clarified by the identification of high-risk disorders (e.g. primary and acquired defects of immunity) and by multi-disciplinary studies of cancer-prone families. (6) Studies are carried out to evaluate the effects of pollutants in the general environment, for example, halogenated hydrocarbons in drinking water. (7) Studies of cancer in domestic animals are conducted in hopes of identifying animal counterparts to human neoplasia. (8) Emphasis is given to multi-disciplinary collaboration with experimentalists to elucidate risk factors (e.g. nutritional, hormonal, viral, genetic) that require laboratory measures.

3.2377,
EPIDEMIOLOGY OF SMOKING-RELATED DISEASES

E.L. Wynder, American Health Foundation Inc., Dept. of Epidemiology, *320 E. 43rd St., New York, New York* 10017

Although it has been well established that there is an association between smoking and certain diseases, not all smokers develop a tobacco-related disease. Variables such as length of cigarette smoked, depth of inhalation, tar output, carbon monoxide content, etc., along with demographic, occupational and other characteristics modify the exposure and risk for a cohort at a given lifetime exposure to cigarettes. The objectives of this case-control study are to identify individuals or groups at risk of tobacco-related diseases, to evaluate environmental, biological and smoking pattern characteristics of persons at high risk, and to analyze the relative effects of cigarette modification. Hospitalized patients who meet study criteria are interviewed by trained research interviewers in selected hospitals in New York, Philadelphia, Birmingham, Pittsburgh, Chicago and San Francisco. Cases are persons with a histologically confirmed diagnosis of cancer of the lung, bladder, pancreas, esophagus or oral cavity, or a first myocardial infarction; patients without a tobacco-related disease serve as controls. Two controls for each case, one from the hospital population and one from the residential area of the case, are matched by race, sex and age. Approximately 1,250 cases and 2,500 controls are interviewed each year.

3.2378,
CANCER MORTALITY IN RELATIONSHIP TO PHENOXY HERBICIDE USE IN WASHINGTON STATE

J.S. Woods, Battelle Memorial Inst., Battelle Human Affairs Research Center, *4000 41st St. N.E., Seattle, Washington* 98105 (02044)

Phenoxyacetic acid herbicides have been widely used in western Washington State as weed control agents for 30 to 35 years. The objective of this study is to determine if there is an association between phenoxy herbicide use in 13 counties of western Washington State and the rate of mortality of various cancers among persons residing in those countries according to area of exposure. Death rates for various cancers and total cancer incidence will be compared by area of residence with estimates of quantity and location of phenoxy herbicide use. Complete information on quantities, times and use patterns of 2,4-D, 2,4,5-T and Silvex from 1945 to 1965 for the area are provided by the Washington Forest Protection Association. Annual age- and sex-adjusted incidence and mortality rates for total cancer and for specific cancers of interest are obtained according to county of residence through the Cancer Surveillance System (CSS) at the Fred Hutchinson Cancer Research Center in Seattle, which contains detailed information on 45,000 cases of cancer occurring between 1974 and the present in the study area. Incidence rates obtained for the CSS registry are being compared with those from the nationwide SEER program to standardize the annual incidence of cancers in study area countries relative to nationwide rates. Standardized cancer mortality rates will be further adjusted for population density, percentage of urbanization and other factors, to determine if altered mortality rates prevail in relationship to herbicide use following adjustments.

EPIDEMIOLOGY OF MYELOMA AND CHRONIC LYMPHOCYTIC LEUKEMIA

N.S. Weiss, University of Washington, School of Public Health & Community Medicine, Dept. of Epidemiology, *4000 15th Ave. N.E., Seattle, Washington* 98105

This case-control study aims to identify and evaluate risk factors for multiple myeloma and chronic lymphocytic leukemia. Cases will be identified through population-based cancer registries in the states of Washington and Utah, and in Detroit and Atlanta, over a three-year period. Control subjects will be selected from the general populations in which the cancer cases occurred, using probability sampling methods such as area sampling and random digit dialing. Cases and controls will be interviewed with particular attention to variables related to chronic antigenic stimulations, e.g. past illnessses, allergies, drugs, etc. Detailed residence and occupational information will also be obtained in an attempt to generate new etiological hypotheses.

EPIDEMIOLOGICAL STUDY OF WORKERS IN PETROLEUM REFINERIES AND PETROCHEMICAL PLANTS

R.J. Waxweiler, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

An NCI study examined the cause-specific mortality experience of workers who were active members of Oil, Chemical and Atomic Workers International Union resident in Texas at the time of death. Proportional mortality ratios (PMRs) for stomach and brain cancers, and for leukemia and multiple myeloma were elevated among white males who worked in petroleum refineries and petrochemical plants and were Union members for at least 10 years. In particular, increased relative frequencies of stomach and brain cancer deaths were found among white male members who were employed at a specific refinery (plant A). In addition, PMRs were elevated for lung cancer among non-whites and stomach cancer in both racial groups employed at another refinery in the same area (plant B). Observed numbers of deaths from leukemia and cancers of the kidney and skin were very small but greater than expected among white males at plant B. A third refinery was found to have excess lung and brain cancers. A case-control study will be done to examine excess deaths from certain cancers in greater detail. Detailed work histories will be obtained for each case and control to determine length of employment in these plants, specific job(s) held, work location(s) within the plants, and any other employment or exposure information that is available. This may be followed by a more definitive cohort study.

THE AMERICAN FAMILY LIFE STUDIES

H.H. Wang, Duke University, School of Medicine, Dept. of Community & Family Medicine, *Box 3711, Durham, North Carolina* 27710

The American Family Life Assurance Company (AFL), a national cancer insurance company, has made its records available for epidemiological research. It currently has 2.7 million policies in force, approximately two thirds of which are family policies. Pathological reports to confirm diagnoses of cancer and detailed descriptions of treatment received are required for receipt of benefits or reimbursement. All this information is microfilmed. A series of studies will be based on these records. The first will be the determination of age- and sex-specific cancer incidence rates in the insured population to serve as the reference rates in the other studies. The second group of studies will be on the occurrence of cancer in spouse-pairs to assess the role of shared environment in the etiology of several cancers, such as Hodgkin's disease, colon, and genital and reproductive tract cancers. The third group of studies will investigate the risk of second primary cancers in relation to different types of therapy. Dose-response relationships will be evaluated for those therapies found to increase the risk of second primary cancers. Other studies will include examination of sibling aggregation in childhood cancer, re-evaluation of the 'cancer family' hypothesis and cancer incidence rates in specific occupational groups.

CANCER MORTALITY AMONG PETROLEUM AND CHEMICAL WORKERS

T.L. Thomas, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205

The objective of this study is to determine whether persons employed in the petroleum and chemical industries experience unusual patterns of cancer mortality indicative of exposure to hazards in the work environment. The study groups consist of deaths among members of labor union that represents a large segment of the petroleum and chemical industries in the USA. Approximately 18,000 deaths among active union members were reported to the central office of the union by the individual local branches between 1947 and 1977. The study period is being extended beyond 1977 as new deaths are reported. A proportionate mortality analysis will be performed to compare the relative frequencies of deaths from specific forms of cancer among union members with the experience of the general population. Occupational information for each subject includes data of entry into union and specific industrial category of the plant in which he worked. The investigation is intended to identify high-risk areas within the petroleum and chemical industries that warrant further examination by more refined epidemiological methods.

WORLD HEALTH ORGANIZATION'S COLLABORATIVE STUDY OF NEOPLASIA AND STEROID CONTRACEPTIVES

D.B. Thomas, Fred Hutchinson Cancer Research Center, *1124 Columbia St., Seattle, Washington* 98104

The objective of this hospital-based, multi-centered case-control study is to ascertain whether there is a relationship, particularly in developing countries, between the use of steroid contraceptives (oral and long-acting injectables) and neoplasms of the breast, cervix, corpus uteri, gallbladder (including also extrahepatic biliary tree), liver and ovary. Standardized techniques to estimate relative risk will be utilized. Approximately two hospital controls will be studied for each case. All (cases and controls) will be interviewed to ascertain prior use of steroid contraceptives and information on other factors related to contraception and the neoplasms under study. Except for suspected liver tumors, all cases will be diagnosed histologically by local collaborating pathologists and reviewed by reference pathologists. The review results and pathology data will be checked, key-entered onto computer tape and edited at the co-ordinating center. It is anticipated that the initial phase of this study will run for five years. This will hopefully provide sufficient cases to: (1) Allow comparisons of results from different collaborating centers for the more common neoplasms; (2) provide information on the rarer neoplasms or histological sub-types by pooling the results from different collaborating centers. In addition, it is tentatively planned to continue this study beyond five years to provide a mechanism for monitoring steroid contraceptives for carcinogenic effects that may become apparent in the future.

EPIDEMIOLOGY OF LUNG CANCER

J.L. Andrews, Harvard University, Boston Campus, School of Medicine, Dept. of Pulmonary, *25 Shattuck St., Boston, Massachusetts* 02115

Lung cancer incidence is increasing dramatically worldwide in both men and women. Etiological factors in diagnosed cases of lung cancer including cigarette smoking, sex and environmental exposures will be investigated in a case-characteristics study. All cases of lung cancer seen in previous studies at a large multi-specialty medical clinic in Boston (Lahey Clinic) from 1956-1972 (Med. Clin. North America, 59, March 1975) were analyzed. Findings are now being updated to 1980 to cover a twenty four year period. A list of all patients with diagnosed lung cancer, giving their sex and age, is obtained from the Lahey Clinic Tumor Registry. Approximately

2,000 patients will be analyzed. There is an increased proportion of women among the total number of patients diagnosed with lung cancer. Further analysis, including scrutiny of the medical record to find smoking and environmental history, and review of pathology slides by the pathologist to confirm cell type of the tumor and Kreyberg classification is made for all women with lung cancer. Preliminary results show that the biggest rise in lung cancer in women is among smokers who have Kreyberg Group 1 (smoking-related) tumors.

EPIDEMIOLOGY OF LEUKEMIA AND LYMPHOMA IN RELATION TO ALTITUDE

H.M. Lemon, University of Nebraska, Medical Center, School of Medicine, Dept. of Internal Medicine, *42nd & Dewey Aves., Omaha, Nebraska* 68105

This investigation has been carried out for the past 15 years and is on-going. Two populations of 110,000-115,000 each are being surveyed for their total leukemia, lymphoma, and myeloma incidence and mortality rates, in 6 counties in Central Nebraska (elevation 600 meters) and in counties in Southwestern Wyoming (elevation 1,800 meters). A two-fold difference in Hodgkin's lymphomas and chronic lymphocytic leukemia have been demonstrated over a decade (lower at higher altitude) without any differences in histiocytic lymphoma or acute or chronic myelogenous leukemia rates. The populations are very similar in race, economic level and occupational exposure to radiation (very low).

EPIDEMIOLOGICAL AND THEORETICAL TOXICOLOGY STUDIES ON CHRONIC ARSENIC POISONING INCLUDING ARSENIC-INDUCED CANCERS

R. Zaldivar, Gerhard Domagk Research Group Cancer Epidem. & Environ. Hyg., *5055 N.W. 7th St., Miami, Florida* 33126

The aims of this project are as follows: (1) to describe dose-response curves for males, females and both sexes combined; (2) to collect data on mean arsenic dose (mg/kg body wt/day) and mean age for males, females and both sexes combined; (3) to collect data on combined as well as dose (mg/worker/day) for male laborers doing hard work; (4) to analyze mean dose (mg/kg body wt/day), mean age, and age-specific prevalence rate per 100,000 population for chronic arsenic poisoning for males, females and both sexes combined; (5) to analyze mean age, prevalence rate and mean dose (mg/person/day); (6) to analyze the sex as a categorical variable; (7) to estimate ingested doses (based on arsenic concentrations in drinking water and foods) in patients with arsenic-induced cancers (skin carcinomata and malignant hemangio-endothelioma of liver); and (8) to apply the compartment theory to the toxokinetics of arsenic. Data on mean doses, mean ages, and sex distribution from 290 normal subjects and 30 laborers have been collected from Antofagasta Commune, Northern Chile. Data processing and statistical analyses are being carried out.

3.2388,

ENVIRONMENTAL CARCINOGENS AND HUMAN CANCER

J.R. Ward, Geomet Inc., Environmental Health Division, *15 Firstfield Rd., Gaithersburg, Maryland* 20760

This project is part of a US Environmental Protection Agency program investigating the relationship between environmental carcinogens and risk of cancer in the general population. Much of the work to this point has concerned problem definition, methodology and data base development. The program is now focussing on geographical areas that can serve as community laboratories for research on environmental levels of specific carcinogens and their association with cancer risk. An area centered in southeastern Ohio has been selected for this purpose after screening over 3,000 US counties for coincidence of high cancer mortality and probable exposure. Preliminary investigations to establish the utility of the study area have been completed. The potential for long-term carcinogen exposure has been confirmed through emission source inventory and analysis of available monitoring data. Intra-area mortality analysis has shown significant differences in respiratory cancer associated with proximity to major emission sources. Results from a small case-control study suggest that the increased risk in these source sectors may be related to long-term residence and smoking, but it does not appear to be due to smoking alone or to occupational exposure. Based on this preliminary work the Agency is proceding with monitoring of carcinogen levels in air, water, soil, flora and fauna, and planning further epidemiological studies.

3.2389,

ENDOGENOUS FACTORS IN BREAST CANCER

E.L. Wynder, American Health Foundation Inc., Dept. of Epidemiology, *320 E. 43rd St., New York, New York* 10017

A major analysis of data on 785 women with pathologically confirmed breast cancer has been published (Cancer, 41, 2341-2354, 1978). History of maternal breast cancer was a significant risk factor, while no significant differences were observed between cases and controls for birthplace, marital status, husband's occupation, religion, or education, or with age at menarche, age at menopause, duration of menses, history of nursing, or parity. A statistically significant increase in relative risk was found among pre- and perimenopausal (but not postmenopausal) women who bore their first child at a later age. No significant differences were found between cases and controls for weight, height, or weight/height, or reported use of any estrogenic drugs, or for any endocrine-related diseases (except for a slight excess of benign breast disease among cases). Studies by us and others have shown that no known endogenous factor can account for differences in breast cancer rates between high and low risk areas of the world. Therefore, exogenous factors must be emphasized, particularly in relation to the influence of nutrition. A comparative study of the epidemiology of breast cancer in the US and Japan was concluded in collaboration with Dr. T. Hirayama (Prev. Med. 6, 567-594, 1977). This study suggests that all American women must, as a practical matter, be considered to be at high risk, and that diet must be considered a causative factor. Because diet is known to affect hormone physiology and breast cancer is a hormone-dependent disease, it is conceivable that nutritional factors may have a significant effect upon breast cancer risk. A metabolic epidemiological investigation is being conducted in Japan, Finland and the US, nations where breast cancer rates and dietary habits are very different. Comparative analysis of serum and breast fluid hormone values from healthy women and breast cancer patients will be performed.

DO SOME GENETIC CONSTITUTIONS PREDISPOSE TO CANCER

H. Punnett, Temple University, School of Medicine, Dept. of Pediatrics, *3322 Broad St., Philadelphia, Pennsylvania* 19122

The serum protease inhibitor alpha 1-antitrypsin (AAT) functions as a phase reactant neutralizer of proteolytic enzymes released from tissues during inflammatory processes. It is also part of the regulatory mechanism of the hemostatic and fibrinolytic systems. Individual serum levels and type are genetically determined by a pair of codominant alleles. An association between a deficiency of AAT and hepatocarcinoma has been suggested based on case reports in the literature. The risk of developing hepatocarcinoma is being evaluated by studying families in which deficiency alleles of AAT are segregating. These are the protease inhibitor (Pi) types I, S, Z and null. Families are identified in many ways: through propositi with neonatal liver disease, chronic pulmonary disease, coeliac disease or serendipity. Detailed family histories are obtained; hospital records and death certificates are obtained where possible. By Pi typing all living members, the Pi types of deceased individuals may often be deduced. It is planned to study a minimum of 100 families. The population under study will be analyzed for an increase in hepatocarcinoma in proven or probable carriers of Pi deficiency genes. Pi normal (MM) individuals in the same families will serve as controls. The two groups will be compared to US mortality statistics. The data will also be analyzed for frequency of many other neoplasms. In addition to defining the frequency of hepatocarcinoma in this population, other factors which may influence the development of malignancy in Pi deficient individuals will be sought.

DIAGNOSTIC CRITERIA AND TECHNIQUES FOR DETECTION OF ASYMPTOMATIC ORAL CARCINOMA - IDENTIFICATION OF HIGH-RISK GROUPS

A. Mashberg, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Dept. of Oral & Maxillofacial Surgery & Oral Oncology, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019

It appears that erythroplastic portions of asymptomatic oral squamous cell carcinoma stain positive with toluidine blue. Very few false positives are found if toluidine blue is used in conjunction with previously defined clinical criteria (erythroplasia). Suspicious oral lesions found during routine oral examinations are referred to the investigator. Lesions which persist for 10-14 days are described, photographed, and a demographic questionnaire is completed by a trained interviewer. A clinical diagnosis is made and the lesion is stained using toluidine blue. Results are recorded. A biopsy renders final pathological diagnosis. Demographic data are being evaluated to delineate what percentage of these patients with oral squamous cell carcinoma drink or smoke heavily, have developed or have had other primaries of the upper aerodigestive tract, including the mouth. It should be noted that these are for the most part independent squamous lesions. Additionally, recurrence and survival rate for patients with early asymptomatic lesions is being studied. A control group is also being studied. All admissions to the hospital have a scheduled appointment for oral examination in the Dental Clinic. Patients scheduled each day (over 40 years of age) are interviewed and questioned. The only bias in selection is that patients who are too ill to attend the clinic are not taken or that patients are inadvertently missed for interview. Since the patients with early erythroplastic oral cancer are those who are examined in the same way, the controls are in the same population.

DETERMINANTS OF CANCER AND CARDIOVASCULAR DISEASE MORTALITY IN ASBESTOS MINING COUNTRIES OF CALIFORNIA

R.A. Ziskind, Science Applications Inc., Energy Environment Systems Division, *1801 Ave. of the Stars, Suite 1205, Los Angeles, California* 90067

The purpose is to evaluate the association of mortality from respiratory tract cancer, mesothelioma, and cardiovascular disease with length of residence in the proximity of natural asbestos formations and processing activities after controlling for the effects of cigarette smoking, occupation, and genetic susceptibility. The study design will define the geographical bounds and causes of death to be investigated. A questionnaire will be used to obtain information from surviving family members. A comprehensive in-

ventory and characterization of stationary, mobile, anthropogenic and natural sources of asbestos will be made in all case and control areas for the time periods of interest. Air and water exposure maps covering the study areas will be constructed and used to correlate personal histories with degree of exposure.

MORBIDITY AND MORTALITY AMONG TACONITE ORE MINERS

I.T. Higgins, University of Michigan, Ann Arbor Campus, School of Public Health, Dept. of Epidemiology & Environmental & Industrial Health, *Ann Arbor, Michigan* 48104

Considerable controversy has surrounded the mining and processing of taconite ore, which contains approximately six per cent iron, and is a major source of the iron used in steel made in the United States. Associated with it is fibrous silica of the grunerite-cummingtonite series. In order to determine if long-term exposure to taconite dust contributed to increased morbidity or mortality among workers, a historical cohort study was initiated in 1976. 5,750 white males having worked for at least one year are being followed. Comparisons with state and national rates for mortality as well as quantification of individual exposure are being carried out.

MORBIDITY AND INDUSTRIAL HYGIENE STUDY OF FIBROUS MINERAL WORKERS

J. Gamble, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Diseases Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505

Exposure to asbestos has long been recognized as being associated with pulmonary pathology, and because of this industry has begun utilizing material other than asbestos. These substitute materials, however, are similar to asbestos in morphology and chemical/physical properties. While a great deal of health research exists about asbestos, insufficient evidence exists on the possible pernicious effect of the substitute materials on the respiratory system. Exposure to these substitute materials will be studied, concentrating particularly on talc but examining other fibrous minerals as well. Representative samples of those exposed to these materials in production or secondary use will be studied through the use of questionnaire, x-ray and measurement of respiratory function. The results will be co-ordinated with industrial hygiene surveys at the places studied. Industrial hygiene examinations of all talc facilities have been completed. All raw data has been received and is awaiting analysis and reports. Preparations have begun for industrial hygiene examinations of the attapulgite clay industry.

MORTALITY, MEDICAL, AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO NITROSAMINES

J. Fagen, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation and Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Dimethylnitrosamine is denoted a carcinogen by the Occupational Safety and Health Administration and appropriate precautions are taken in the few areas where it is used or manufactured. New analytical techniques have shown that dimethylnitrosamine and other nitroso compounds may form under appropriate conditions in the ambient atmosphere or even in vivo if sufficient concentrations of precursors (secondary amines, amides, etc.) and nitrates, nitrites or other nitrogenous compounds exist. 28 plants have been investigated during 40 industrial hygiene surveys for possible nitrosamine contamination. The industries visited were the automobile, azo dye, fish and fish meal, rubber, leather and small machine shops. To date N-nitrosodiethanolamine, N-nitrosodimethylamine, N-nitrosomorpholine and N-nitorosodiphenylamine have been found in the air of several plants. N-nitrosodimethylamine, a regulated carcinogen, was found as high as 50 ug/cbm in the leather industry: N-nitrosomorpholine was in the rubber industry at 27 ug/cbm. Efforts were made to determine the nitrosating agent, source of contamination, the extent of human exposure and methods of controlling the exposure to nitrosamines in the rubber and leather industries.

MORTALITY, MEDICAL, AND INDUSTRIAL HYGIENE STUDY OF GOLDMINERS EXPOSED TO ASBESTIFORM MINERALS

D.P. Brown, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation and Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

The NIOSH-recommended standard in 1972 for asbestos exposures of 2.0 fibers longer than 5 um per cubic centimeter of air (fibers greater than 5 um/ccm) was made with the recognition that health data for exposure to low fiber levels and definitive information on the biological response to different size fibers were not available. NIOSH in 1976 recommended a standard of 0.1 fibers greater than 5 um/ccm. In 1976 NIOSH reported on a mortality study of a mining population exposed to amosite asbestos (cummingtonite - grunerite) concentrations below 2.0 fibers greater than 5 um/ccm and with most fibers being shorter than 5 um in length, that demonstrated significantly increased mortality due to both malignant and non-malignant respiratory disease. The purpose of this project is to complete an expanded retrospective mortality study.

EXCESS GALLBLADDER CANCER IN THE HISPANIC POPULATION OF NEW MEXICO

R.W. Buechley, University of New Mexico, School of Medicine, Cancer Research & Treatment Center, *University Hill N.E., Albuquerque, New Mexico* 87131

Historical records indicate that the Hispanic population of the State of New Mexico is 'Mestizo', with both American Indian and Caucasian ancestry. Population genetic studies reveal that the American Indian component is greater than 40 per cent. Evidence now exists that gallbladder cancer is characteristically an American Indian or Mongoloid disease. Both American Indian and Japanese women display unusually high incidences. The diversity of their cultures, diets, and environments suggests that gallbladder cancer has a strong heritable component. The genetic similarity between American Indians and Hispanics further suggests that the disease occurs in Hispanics as a result of their American Indian admixture. A population-genetic study of a Rio Arriba County Hispanic village has shown strong marital isolation, high inbreeding, and many individuals who are homozygous for a number of HLA antigens. Two familial cases of gallbladder cancer, the first reported in the literature, have been found, one involving mother-daughter-cousin and the other involving two sisters. Additional familial cases in Rio Arriba County are now being sought to establish the pattern of inheritance of the factor, or factors, predisposing its population to gallbladder cancer.

ETIOLOGY OF CHILDHOOD BRAIN TUMORS

A. Leviton, Childrens Hospital Medical Center, Dept. of Neuroepidemiology, *300 Longwood Ave., Boston, Massachusetts* 02115

The purpose of this case-control study is to identify risk factors for the most common subtypes of the three most common site-specific brain tumors (cerebellar gliomas, medulloblastomas and supratentorial gliomas). Cases consist of all children with these types of brain tumors identified within the catchment areas of the eight participating SEER (Surveillance, Evaluation and End Results) Registries between 1/1/78 and 12/31/81. Three controls will be obtained for each case through Random Digit Dialing and will be matched for age (3 years), sex and race. Parents of cases and controls are asked by questionnaire to

provide information on the numerous exposures that might influence the risk of brain tumors in children. The null hypothesis to be tested is that each variable has the same distribution among cases and controls.

TREND IN LUNG CANCER MORTALITY RATES IN PHILADELPHIA, PA, USA

W. Weiss, Hahnemann Medical College & Hospital, Medical College, Dept. of Medicine, *235 N. 15th St., Philadelphia, Pennsylvania* 19102

The number of lung cancer deaths in Philadelphia has increased from 517 in 1955 to 1,025 in 1977 although the total population has fallen from 2.2 million to 1.9 million. Rates adjusted to the 1960 census have been calculated for white and non-white males and for white females. The number of cases in non-white females is too small to provide stable rates. The trend for males of both race groups since 1955 has shown a strong tendency to plateau in recent years while the trend in white females has continued upward steadily. The decrease in the rate of increase in males seems to be much more marked in Philadelphia than in US males. Observation continues.

RELATIONSHIP BETWEEN HUMAN PAPOVAVIRUSES AND TUMORS OF THE NERVOUS SYSTEM (ABBREV)

E. Beth, Memorial Sloan Kettering Cancer Center, Immuno Virology Section, *1275 York Ave., New York, New York* 10021

Human papoviruses, particularly JC virus, can transform hamster and rat cells in vitro and can induce tumors in vivo when injected in hamsters and monkeys. The JC virus induces mainly tumors of the nervous system, and has been clearly shown to be the etiological agent of progressive multifocal leucoencephalopathy (PML), a demyelinating disease. The main objective of the project is to establish an association between the above mentioned viruses and malignancies of the nervous system by extensive sero-epidemiological studies. The immunovirological antibody profile against early and late antigens determined by papovaviruses is established in sera of cancer patients with tumors of the nervous system from USA, Europe, and North Africa. Two sex- and age-matched (2-5 years) healthy controls, living in the same areas and in similar socio-economic conditions, are used for each patient. A second control group will consist of serum samples from age-and sex-matched patients with a cancer of different origin and location but similar therapy.

NORTH-EAST FLORIDA LUNG CANCER STUDY

J.E. Davies, University of Miami, School of Medicine, Dept. of Epidemiology & Public Health, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152

This study proposes to gather retrospective data concerning asbestos exposure on all new lung cancer cases in four north-east Florida counties. The study will consider occupational histories as well as smoking. The study will also locate geographically all cases and two matched controls to ascertain any possible clustering patterns associated with major air pollution sources in the area. Case verification has been performed by an independent pathology review and analysis is anticipated concerning morphological types of lung cancer and specific risk factors. The study is also identifying mesothelioma and asbestosis cases for the same time period (1978-79) and geographical area.

LUNG CANCER IN A COHORT OF WELDERS

J.J. Beaumont, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Welders constitute approximately one per cent of the United States male workforce, and on a daily basis they are exposed to a variety of metal oxides, gases, and other substances evolved from the welding process. To assess their lung cancer mortality, a cohort of 3,247 welders with at least three years experience was established from the records of a metal trades union representing workers in shipyards, metal fabrication ships, and field construction. Comparison has been made with death statistics and preliminary results indicate an excess lung cancer rate of 31 per cent, which increases to 69 per cent when only those person-years after 20 years latency are considered.

MORTALITY, MEDICAL AND INDUSTRIAL HYGIENE STUDIES OF PRINTING TRADES

D. Zaebst, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Johns Hopkins University is investigating the extent and nature of health effects occurring in populations engaged in the application of surface coatings. A carefully selected cross-section of industrial settings (wood furniture, railroads, aircraft, automobile, etc.), and of paint and coating systems (each with its own peculiar hazard potential) and application techniques, will be evaluated. The project consists of three closely interrelated phases: epidemiological studies, cross-sectional medical studies, and industrial hygiene studies. Preliminary surveys were completed in a total of 48 plants or construction sites in 1979 and an undetermined number of these will now be selected for in-depth studies.

PHOTOCHEMOTHERAPY FOLLOW-UP STUDY

R.S. Stern, Harvard University, Boston Campus, School of Medicine, Dept. of Dermatology, *25 Shattuck St., Boston, Massachusetts* 02115 (01988)

This prospective cohort study is assessing the risk and efficacy of oral methoxsalen photochemotherapy, introduced in 1974 for the treatment of psoriasis, and now widely used for this common skin disease. On the basis of basic science and animal experiments, there is concern about its potential long-term toxicity, especially cutaneous carcinogenesis and cataract formation. Treatment requirements, extent of control of the patient's disease, and the incidence of adverse events, especially skin cancers and cataracts in this population, are being documented. This is a 16 center cooperative follow-up study. Data are collected on patients prior to entry and at annual intervals. Each of the 1,380 patients in the cohort is invited to be examined by a dermatologist and interviewed. The cohort will be followed for an average of six years from first treatment to the proposed end of the study. Historical controls are used. In addition, since side effects are expected to be dose-related, the incidence of adverse events in photochemotherapy will be compared.

PRELIMINARY STUDY ON THE EPIDEMIOLOGY OF MENINGIOMAS

R.S. Lin, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201

The objective is to identify risk factors for meningioma with special emphasis on the use of hair-dyes. The possible etiological factors of trauma, irradiation, infection, sex hormones and drugs, hereditary factors and other environmental exposures will also be assessed. A retrospective case-control method by means of mailed questionnaires is used, cases being meningioma patients diagnosed at the University of Kansas Medical Center. For each female case, three control patients without cancer, matched for race and year of birth, are selected from the name-roster at the Breast Cancer Detection Center of the University of Kansas Medical Center. Preliminary analyses from the collected questionnaires of 41 female cases with meningioma and 86 controls show that meningioma cases reported themselves exposed to hair-dyes less frequently than the controls. However, meningioma cases exhibit a significantly higher body weight and body mass index (RMT) at age 40 than the controls. In addition, more cases than controls come from large families and suffer from thyroid diseases. The epidemiological findings as well as the well known clinical evidence of a female preponderance in meningiomas seem to suggest that hormonal factors may play an important role in the pathogenesis. Further exploration of the association with hormonal imbalance or obesity is planned.

PILOT STUDY ON THE NATURAL HISTORY OF BLADDER PAPILLOMAS

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201

A major dilemma in urological practice today is the inability of physicians to predict which benign appearing bladder papillomata will eventually invade and which will not. An epidemiological study has been undertaken to investigate this problem. A sample of Baltimore area urologists are participating in an investigation of all their patients recently diagnosed as having bladder papillomas or early stage carcinomas. The biopsy and other tissue specimens are being analyzed in detail by Dr. Joseph C. Eggleston. Their urological and medical records are being reviewed and all patients are being interviewed with respect to known and potential bladder carcinogen exposure. It is hoped that this study will it possible to correlate the histological characteristics and exposure histories of the bladder tumor patients with their subsequent clinical course. At this time, 22 or 9.1% of 243 papilloma patients have been found to develop bladder carcinoma after precursor papillomas. These appear more likely to be smokers, and to have histories of certain environmental exposures than do other papilloma cases. The papillary lesions associated with subsequent malignant transformation are not readily distinguished from others. The data are now being analyzed with respect to: (1) the incidence and prevalence of bladder papillomas in the Baltimore area; (2) the incidence or probability of developing bladder and other cancer according to host and lesion characteristics; (3) the survival experience of papilloma patients, and (4) the multivariate predictor, based on host factors and papillary lesion characteristics, for events following papillomas.

LEUKEMIA AND NEOPLASMS OF LUNG AND OTHER ORGANS IN A GENERAL POPULATION LIVING IN AN AREA CONTAMINATED WITH LOW LEVELS OF PLUTONIUM

C.J. Johnson, Jefferson County Health Dept., *260 S. Kipling St., Lakewood, Colorado* 80226

A population of 595,226 people live in an area contaminated by a nuclear weapons plant with low levels of plutonium and other transuranic nucleides since 1953. There is evidence that plutonium and other transuranic nucleides are potent carcinogens. A retrospective cohort study will evaluate cancer morbidity and mortality patterns in this population. Data will be controlled for age-distribution, sex, race, ethnic group and possible confounding factors such as air pollution, urbanization, income, occupation, education and immigration will be considered. Cancer incidence data from the Third National Cancer Survey of the National Cancer Inst. for the periods 1969 to 1971 in the Denver Standard Metropolitan Statistical Area will be studied. Cancer death rates for exposed populations will be compared to unexposed populations for the period 1970-1980. An estimated six million persons/year of exposure will be available for study. The source of the data will be death certificates from the Division of Vital Statistics of the Colorado Department of Health and cancer incidence data from the National Cancer Institute, the Colorado Cancer Registry, and the Colorado Regional Cancer Center. The control group is the general population (423,860) residing in the Denver Standard Metropolitan Statistical Area outside the area known to be contaminated with plutonium and other transuranic nuclides. This population has been shown to have virtually the same age-adjusted annual cancer incidence rate as the state of Colorado.

MALIGNANT MELANOMA AND ENVIRONMENTAL EXPOSURE

T.E. Aldrich, University of Miami, School of Medicine, Dept. of Epidemiology & Public Health, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152

This is a non-concurrent, prospective study of environmental exposure to petroleum residues (from conbustion) and the risk of malignant melanomas. Industrial workers considered to be at high risk (e.g., flight line workers, toll booth operators) will be studied in contrast to workers exposed to sunlight (e.g., telephone company employees) or to petroleum residues only (e.g., auto mechanics). Communities in proximity to sources of exposure (e.g., airports, highways) will also be studied, in contrast to communities not so exposed, for melanoma rates. An anticipated 800 persons will be included from industry with an additional study population being the communities studied from institution records only.

STEROID-RELATED TUMORS OF THE LIVER

W.M. Christopherson, University of Louisville, School of Medicine, Dept. of Pathology, *101 W. Chestnut, Louisville, Kentucky* 40202

Clinical data and pathological material are being collected on young women with both benign and primary malignant tumors of the liver. To date about 250 such cases have been examined, the vast majority being related to oral contraceptives or to long-term estrogen use. A number have occurred in late pregnancy or the early post-partum period. In addition to epidemiological data, drug usage, etc., alpha-1-antitrypsin (which seems to be a marker for these tumors), hepatitis antigens and estrogen receptors are being investigeted. Since histological material is available on all cases, the tumor types are well controlled and considerable material will soon be available for further epidemiological studies.

3.2.17,

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO STYRENE

J.J. Beaumont, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Recent research indicates that workers exposed to styrene may experience chronic health problems: (1) There have been studies which show a definite increase of death due to leukaemia among styrene-butadiene rubber workers; (2) Styrene has been shown to be mutagenic after liver microsomal activation; (3) Styrene oxide, which is a metabolite of styrene, has been shown to be mutagenic by the Ames test. hepatoxicity and carcinogenicity have been attributed to chronic exposure to styrene metabolites based on animal experiments. a retrospective mortality and industrial hygiene study of workers exposed to styrene is thus being conducted to further evaluate the potential medical effects of styrene. Preliminary industrial hygiene and record assessment evaluations have been conducted at 15 boat manufacturing facilities, both in and outside the state of Washington, in order to judge the feasibility of their inclusion in the epidemiological study. Two in the State of Washington were identified as appropriate for the mortality study, and five others were chosen for industrial hygiene monitoring alone. A total of seven industrial hygiene surveys were carried out. Demographic files have been coded and are being verified for the retrospective mortality study. Vital status follow-up has begun for all individuals who have worked at the two facilities which are part of the epidemiological study.

3.2.18,

RELATIONSHIP BETWEEN HERPES VIRUSES AND CERTAIN HUMAN MALIGNANCIES

G. Giraldo, Memorial Sloan Kettering Cancer Center, Immuno Virology Section, *1275 York Ave., New York, New York* 10021

There is increasing evidence that herpes viruses play a role in the induction of some human cancers (e.g., EBV and Burkitt's lymphoma; nasopharyngeal carcinoma; HSV-2 and cervical cancer; CMV and Kaposi's sarcoma). The main objectives of the project are: (1) To establish an association between the above-mentioned viruses and malignancies by seroepidemiological studies in high and low risk populations; (2) to analyze whether susceptibility to skin cancer can be shown by immunogenetic studies (HLA and MLC) in a high risk population, Tunisian xeroderma pigmentosum patients; (3) field studies in high incidence areas of Kaposi's sarcoma to detect time-space clusters; (4) retrospective analyses of Kaposi's sarcoma patients to determine if Kaposi's sarcoma is more often associated with a second primary cancer than other cancers. Seroepidemiological studies establish the antibody profile against early and late antigens for herpes viruses in cancer patients and controls. Kaposi's sarcoma cases derive from Uganda, Cameroon, Tunisia, France, USA and Italy; skin cancer from xeroderma pigmentosum patients in Tunisia; penile carcinoma from Uganda. Two sex-matched and age-matched (plus or minus 2-5 years) healthy subjects, living in the same areas and in similar socioeconomic conditions, will be used as controls. A second control group will consist of serum samples from age- and sex-matched patients with a cancer of different origin and location but similar therapy.

RARE SITES CANCER STUDY

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201

The objective is the collection, in five metropolitan areas of the United States, of epidemiological data on persons diagnosed as having one of a number of relatively rare cancers. The sites include the vagina, vulva, penis, testis, scrotum, male breast, renal pelvis, adrenal gland, gall bladder, liver, pancreatic islet cell and nasopharynx. All cases diagnosed over the period of study together with an equal number of controls matched by age, sex and race were interviewed in the hospital. The questionnaire included a very detailed investigation of sexual, genital, marital and hormonal factors as well as a large number of environmental agents of possible importance in the pathogenesis of these rare neoplasms. A total of 1,812 rare cancer patients and controls have been identified and interviewed.

MORTALITY AMONG U.S. COAST GUARD MARINE INSPECTORS

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205

The Coast Guard is involved in the internal inspection of merchant vessels in the United States. During this work, marine inspectors are exposed to a variety of substances (e.g., benzene, trichloroethylene, vinyl chloride, carbon tetrachloride, fuels, pesticides, and others) carried by these vessels. Many of these substances are known or suspected human carcinogens. A cohort follow-up study of approximately 7,000 officers in the marine inspection service between 1942 and 1970 is underway. Cause-specific mortality rates will be compared with rates among other Coast Guard officers (of comparable age, length of service, race, and sex) who were not marine inspectors. Stratification by geographical location of station and length of service will be used to identify hazardous substances, exposure gradients, and latent periods.

RADIONUCLEIDE LEVELS IN MILK AND PREGNANCY OUTCOMES IN WISCONSIN (1963-75)

H.R. Bertell, Ministry of Concern for Public Health, Dept. of Health Research, *151 East St., Buffalo, New York* 14207

About 845,000 pregnancy outcomes are being examined over a 13-year period in Wisconsin to see whether there is any indication of an association with changes in levels of strontium 90, cesium 137 or iodin 131 in milk. Monitoring of radionucleides is done by the State of Wisconsin and published separately for each of six milkshed regions. Wisconsin State Health Statistics for the six milkshed regions are being used to establish maternal/child health trends in the six regions. Two health indicators are examined: (1) death rate for infants with birth weight under 2,500 grams; and (2) percent unsuccessful pregnancies, defined as a pregnancy of 20 or more weeks gestation terminating in offspring death prior to one year. Environmental factors such as the paper and pulp industry, chemical manufacturing plants, fossil fuel generators and occurrence of German measles are also being examined as possible causal agents or co-causal agents of maternal/child health changes observed.

ENVIRONMENTAL RISK FACTORS FOR NASOPHARYNGEAL CARCINOMA IN MALAYSIA

R.W. Armstrong, University of Hawaii System, Manoa Campus, School of Public Health, Dept. of Community Health Development, *Spalding Hall, Room 255, Honolulu, Hawaii* 96822

The study aims to clarify evidence for an association between poorer socio-economic environments and nasopharyngeal carcinoma (NPC), and test the hypotheses that inhaled carcinogens in certain occupational settings and exposure to Cantonese salted fish are high risk factors for this cancer. The individual environments of 100 Chinese and 25 non-Chinese patients with NPC will be compared in order to identify particular patient-environment interactions that may play a part in the etiology of NPC. Relative risk will be computed using 125 controls sampled from the general population. The time and space dimensions of self-specific environments for family members will be established using daily activity patterns spread over one week. Structured and non-structured interviewing techniques will be employed. Field work will be carried out during the first year of the 24 month study in the State of Selangor, Malaysia, and data processing and analysis during the second year in Hawaii.

CANCER MORBIDITY AND MORTALITY IN PREVIOUSLY ANTICOAGULATED PATIENTS

J.F. Annegers, Mayo Clinic, Dept. of Medical Statistics & Epidemiology, *200 1st St. S.W., Rochester, Minnesota* 55901

The speculation that anticoagulant therapy may alter the incidence or mortality of cancer prompted this investigation. A cohort of 376 patients who were residents of Rochester, Minnesota, who had their initial myocardial infarction diagnosed between 1945 and 1969, and who received anticoagulant therapy for at least six weeks, were followed to determine in their cancer morbidity or mortality differed from that expected. The expected number of incidence cases of new malignancies will be derived from the age- and sex-specific Connecticut Tumor Registry rates and the Olmsted County experience, and the number of deaths from Minnesota mortality rates.

PRIMARY INTRACRANIAL NEOPLASMS IN ROCHESTER, MINNESOTA, 1935-1978

J.F. Annegers, Mayo Clinic, Dept. of Medical Statistics & Epidemiology, *200 1st St. S.W., Rochester, Minnesota* 55901

This study is expected to provide data on the incidence of intracranial neoplasms in the population of Olmsted County from 1935 through 1977. The incidence rates will be described by histological type, age, sex and time period. In addition of symptomatic tumors discovered during a patient's lifetime, the age- and sex-specific prevalence rates of brain tumors found at autopsy will be determined. In addition to providing incidence rates of brain tumors, this study will address the implications of cases diagnosed incidentally at autopsy.

3.2427,

PATTERNS OF OTHER NEOPLASIA IN PATIENTS WITH ENDOMETRIAL CARCINOMA

J.F. Annegers, Mayo Clinic, Dept. of Medical Statistics & Epidemiology, *200 1st St. S.W., Rochester, Minnesota* 55901

The 1,191 patients who had their initial treatment for endometrial carcinoma at the Mayo Clinic between 1953 and 1972 are being followed to determine their experience of subsequent malignancies. Approximately 12,000 person-years of post-endometrial carcinoma observation are expected. Numbers of subsequent malignancies will be compared with expected numbers derived from both the incidence rates of the Connecticut Tumor Registry and the incidence rates from our Olmsted County studies. The relative risks of other sites, particularly breast, will be evaluated by the duration from diagnosis of endometrial carcinoma. Patients will also be evaluated by specific risk factors present at the time of diagnosis of the endometrial carcinoma, specifically parity and obesity. These data will make it possible to evaluate whether or not an increased risk of breast cancer may be due to the endometrial carcinoma per se or due to the association of both breast and endometrial carcinomas to common risk factors.

INVESTIGATION OF CANCER CLUSTER

T.E. Aldrich, University of Miami, School of Medicine, Dept. of Epidemiology & Public Health, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152

The object of the project is to identify possible environmental determinants of case aggregation as a 'lead' to further etiological studies. This is a research project designed to respond to reports of cancer clustering. The study protocol describes the steps which will be followed from the intial report to the final conclusion of the specific investigation. Reports involving environmental associations only are accepted. Familial reports are excluded due to complexity. The use of non-case data is included as a means of specifying the case exclusive traits, although there is not a control group strategy.

3.2429,

COLORECTAL CANCER AMONG CALIFORNIAN MORMONS

J.E. Enstrom, University of California, Los Angeles Campus, School of Public Health, *405 Hilgard Ave., Los Angeles, California* 90024

Based on analysis of church records, religiously active Mormon males in California and Utah compared with US white males have a standardized mortality ratio of 60% for colon cancer, 40% for rectum cancer, and 55% for colorectal cancer. Active Mormons abstain from tobacco, alcohol, and caffeine by church proscription. However, the specific reasons for their low colorectal cancer rates are unknown. A prospective epidemiological study using a questionnaire survey to obtain data on demography, lifestyle, diet, occupation, and medical history relevant to colorectal cancer etiology will be carried out on about 20,000 active Californian Mormons, who will subsequently be followed for mortality over a four-year period. Church-based mortality rates covering the years 1960-67 and 1976-79 will also be ascertained for all 350,000 California Mormons to supplement the existing rates 1968-75. In addition to intra-Mormon comparisons, the active Mormons as a whole will be compared with other Californian, US, and international populations, already studied with respect to colorectal cancer. A correlation analysis of extensive dietary and lifestyle data from the 1971-73 US Health and Nutrition Examination Survey with US and Californian colorectal cancer mortality rates will be made by country of birth and state of residence. Several etiological variables of interest, including beef, fat, fiber, and beer consumption, will be examined for consistency with international correlations and previous epidemiological findings. Special emphasis will focus on Spanish-Americans born in Mexico, who have colorectal cancer death rates as low as those of active Mormons.

CASE-CONTROL STUDY AND OPHTHALMOLOGY SURVEY

E. Egan, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation and Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

In response to an employee request, NIOSH began an investigation into an alleged cancer hazard at a chemical plant in Belle, West Virginia. Subsequently, NIOSH received the report of an epidemiological study by that company that demonstrated an excess risk of cancer of the eye, kidney and lung among employees at the plant. In order to thoroughly investigate the causes of this excess cancer risk, NIOSH proposed to conduct an ophthalmological survey of a cross-section of workers at the plant and a case-control study of the eye and kidney cancer cases. The ophthalmological survey was conducted from 13 March 1978 to 21 April 1978. A total of 1,153 persons was examined. One additional case of ocular melanoma was discovered in a pensioned employee. A follow-up of persons discovered in the course of the survey to have pigmented lesions of the optic fundus is planned for 1980. The work histories of all the eye and kidney cancer cases identified at the plant will be compared to the work histories of a group of matched controls to determine if the cancer cases worked more frequently than the controls in any specific job areas.

USE OF PARITY SURVIVORSHIP ANALYSIS IN THE SEARCH FOR OCCUPATIONAL CARCINOGENS

J.G. Dobbins, University of Texas, Medical Branch at Galveston, School of Medicine, Dept. of Preventive Medicine & Community Health, *300 University Blvd., Galveston, Texas* 77550

Many occupational carcinogens are also teratogens, and exposure to these substances during pregnancy will result in increased rates of spontaneous abortion. This increase will in turn augment the time required to progress from one parity to the next. Simulation is being used to determine if the increase in time between births is sufficiently large to be detected in view of the effects and variation of other variables such as lactation, post-partum amenorrhoea, fecundity, and contraceptive behavior. The time delay between parities is estimated using life table techniques to follow women from date of delivery of one parity to the next parity. As many women never progress to the next parity, the mean time, median time, or 'life expectancy' at the initial parity cannot be calculated. Instead, a 'life expectancy' is calculated for a five-year period following the initial parity. This value represents the average number of months out of a possible 60 months during which women remain at their initial parity. Finally, the power of analyzing this time estimate is compared to the power of analysis of more traditional measures of fetal loss.

LATE FOLLOW-UP OF CURED WILMS' TUMOR PATIENTS

G.J. D'Angio, Childrens Hospital of Philadelphia, Childrens Cancer Research Center, *3400 Civic Ctr. Blvd., Philadelphia, Pennsylvania* 19104

The objectives of this portion of the National Wilms' Tumor Study are (1) to study the delayed adverse affects of therapy including impaired function of various organs, and oncogenesis, and (2) to seek clues as to etiology by looking for patterns of familial disease in parents and siblings with a view towards identifying possible genetic and environmental factors. At present approximately 300 long term survivors are seen regularly in follow-up, and this number will increase by about 110 children annually for the next three years.

INDUSTRIAL HYGIENE AND MORTALITY STUDY OF CRUSHED STONE WORKERS

J. Costello, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (02134)

As a result of finding asbestos fibers in crushed rock being quarried in Maryland, negotiations were started and are continuing with the National Crushed Stone Association for NIOSH to do a national mortality study of workers in this industry. Emphasis will be placed on causes of death related to cancer and pulmonary diseases, comparison being made with the U.S. national average for white males, and with white females for each of the states in which a quarry is visited. If large numbers of black workers are found the control populations are adjusted accordingly. As an integral part of this study, the Environmental Investigations Branch will examine and characterize the four basic types of rock being quarried. Preliminary surveys have been carried out in several quarries and data have been collected from five quarries. Arrangements have been made to collect data in three additional quarries.

MORTALITY AMONG JEWELRY MANUFACTURERS

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205

Workers in the jewelry manufacturing industry may be exposed to solvents, acids, waxes, talc, and metal fumes and dusts. To evaluate the mortality experience of persons exposed to such substances (some of which are known carcinogens), a cohort follow-up study of 15,000 members of the Jewelry, Diamond, and Watchcase Workers Union has been initiated. Cause-specific mortality rates will be compared to expected rates based on the local and general US populations. Stratification of the cohort by date of entry into the Union, job title, and duration of membership will provide an indication of exposure gradients and latent periods.

MORTALITY AMONG CLINICAL LABORATORY TECHNOLOGISTS IN THE STATE OF CALIFORNIA

D.J. Grauman, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205

Medical technologists are routinely exposed to chemicals used in the preparation, fixation and staining of biological materials. Although chemicals such as chromium, benzidine, toluene, formaldehyde and chloroform, which are used in some of these processes, have been shown to be carcinogenic in animals, the cancer experience of this occupational group has not been well investigated. A unique data resource suitable for such an epidemiological study is available from the State of California which has been licensing medical technologists annually for approximately 40 years. It is proposed to observe the long-term mortality experience of a cohort of medical technologists and compare it to that of one or more suitable control groups. Life table analysis will be used to compare observed numbers of deaths from specific causes among medical laboratory technologists to 'expected' numbers of deaths derived from the experience of the control group(s). Adjustments will be made for differences in age, sex, race, and time of death of the cohort and the control group(s). Observed and expected numbers for each cause of death will be compared statistically to determine whether or not differences are due to change alone.

PROSPECTIVE STUDY OF CANCER EPIDEMIOLOGY

S. Graham, State University of New York, Buffalo Campus, School of Social Science & Admin., Dept. of Sociology, *3435 Main St., Buffalo, New York* 14214

Most epidemiological knowledge of cancer has been generated by retrospective inquiry, and it is likely that the data generated are reliable. To provide additional tests a prospective design on a large population has been devised. The study will be concerned especially with cancer of the larynx, lung, breast, corpus, colon and prostate. Various facets of diet, including the relationship with ingestion of meats, fats, cruciferous vegetables, fiber, vitamins A, C, and E, coffee and alcohol will be examined. Data on a few other known risk factors, e.g. tobacco, will be obtained to examine interaction between them and dietary parameters, e.g. the association of vitamin A with a reduction in risk among heavy and light smokers. The study population consists of individuals aged forty and older within a group of approximately 187,000 nurses, and 51,000 physicians licensed in New York State in 1979. Their names, ages and addresses will be on file. The New York State Tumor Registry gathers data on a variety of parameters and enters them for each individual on computer tape. The computer tapes of the nurse and physician population who have participated in the inquiry will be matched with those of the Tumor Registry to obtain individuals with like names, dates of births, ages, and addresses to follow the cancer status of the study subjects. Data are collected by mailed questionnaire containing easily filled out, pre-coded questions on height and weight, smoking, amount and type of cigarettes smoked, alcohol ingested, and a very abbreviated diet questionnaire obtaining frequency of ingesting the major cruciferous vegetables, sources of vitamins A, C, and E, meats, and fats, fiber, and vitamin pills. The questionnaire will be mailed by December 1979.

HUMAN GENETICS EPIDEMIOLOGY ANALYSIS

S. Graham, State University of New York, Buffalo Campus, School of Social Science & Admin., Dept. of Sociology, *3435 Main St., Buffalo, New York* 14214

There is a need to examine both the environmental and genetic variables in the epidemiology of cancer and ultimately to examine the interaction of the two kinds of aetiological factors. Although a number of pedigree studies have been done, relatively little has been done to study genetic factors in cancer in large series of cases and controls. Analyses have been initiated to examine the heritability of cancer at various sites as studied in large series. Current studies are designed to obtain data on name, age and address of case and controls or, if dead, the last addresses of their parents, siblings, and offspring. Armed with these data, a clerk selects matches from the computer printouts of the Tumor Registry in Albany. When a relative is found to be a case, interviewers are assigned to interview the other relatives of that case to identify and other kin with cancer of the site under study. Dr. William Duggleby, a human geneticist, conducted a preliminary analysis on a series of melanoma cases and controls hospitalized at Roswell Park Memorial Institute. Controls are matched on age (plus or minus 5 years) and sex and have neoplasms probably unrelated to melanoma. They are selected from thoracic, breast, gastrointestinal, genitourinary and medical services. This examination of 214 cases and 1,134 relatives and 193 controls and 1,043 relatives indicated and 8- to 12-fold increase in risk for persons with melanoma in their first degree relatives. Interviews of kin with cancer suggested a possible polygenic mode of inheritance. A paper on this is being prepared. It is planned to analyze in a similar fashion series of cases and controls for sites including testis, mouth, oesophagus, stomach, colon, rectum, lung and bladder.

POPULATION-BASED CASE-CONTROL STUDY OF RESPIRATORY CANCER AND EMPLOYMENT HISTORY

E.R. Glazer, State Dept. of Health Services, Resource for Cancer Epidemiology, *1450 Broadway, Oakland, California* 94612

The objective of this study is to assess the effectiveness of a retrospective population-based study as a tool for the surveillance of occupational cancer. Detailed information on occupational and smoking histories and other relevant variables will be obtained for all respiratory cancer cases generated in one year by a geographically defined population of approximately one million. Past incidence trends indicate that this should amount to some 600-700 cases. Questionnaires will be administered to cases as soon as possible after diagnosis. One control, matched for sex, race, 10-year age group, and area of residence, will be selected for each case.

RE-ANALYSIS OF THE TRISTATE LEUKEMIA SURVEY DATA WITH SPECIAL REFERENCE TO THE LEUKEMOGENIC POTENTIAL OF DIAGNOSTIC X-RAYS

M.E. Ginevan, Argonne National Lab., Division of Biological & Medical Research, *9700 S. Cass Ave., Argonne, Illinois* 60439

The data under study consist of 1,414 adult leukemia cases and 1,370 controls matched for age and sex. Earlier analyses of the data suggest considerable uncertainty as to the exact nature of this association. Analyses to date suggest that there is a precipitous increase in risk of myelogenous leukemia in males exposed to 40 or more X-ray films within a 10-year period. This apparent association is being investigated to determine its exact nature. Among the hypotheses being examined is that the excess leukemia risk is a result of preleukemic conditions which elevate the probability of being X-rayed (i.e. leukemia causes X-rays) versus the possibility that ill health results in X-rays being taken which cause leukemia. To this end the disease histories of leukemia cases and controls are being compared, as are the temporal aspects of their X-ray exposure histories. A complete re-analysis of the entire data set is also being carried out, which it is hoped will contribute significantly to the understanding of low level, low linear energy transfer, radiation risks.

SURVEILLANCE OF HEALTH EFFECTS OF POTENTIALLY LESS HAZARDOUS CIGARETTES

G.D. Friedman, Kaiser Foundation Research Inst., Dept. of Medical Methods Research, *1956 Webster St., Room 310 B, Oakland, California* 94612

This is a prospective epidemiological study designed to investigate the health effects of smoking, with particular interest in the recently introduced smoking products which have reduced yields of selected toxic constituents. Hypotheses are to be tested regarding significant differences between health effects of the older and newer smoking products. A self-administered questionnaire is being completed by all Kaiser health plan subjects who are given a multiphasic health checkup (MHC) at the KFRI Oakland-San Francisco facilities during the two-year period March 1979-February 1981. It is expected that approximately 50,000 subjects will be involved annually. The questionnaire contains detailed questions on smoking habits, as well as more general questions on occupation, demographic/socio-economic characteristics, and dietary practices. Questionnaire responses, in conjunction with mortality and morbidity data (hospitalization, physician visits, days of incapacitation) and MHC data, are to be analyzed for relationship between smoking habits and adverse health effects. This study is planned initially to cover a three-year period (two years of data collection, one year for follow-up and analysis). However, the ground-work is being established for a long-term follow-up if this becomes desirable at some future date.

THE EFFECTS OF LOW LEVEL GAMMA AND ALPHA RADIATION ON PERIPHERAL BLOOD LYMPHOCYTE CYTOGENETICS AND SPUTUM CYTOLOGY

S.W. Ferguson, State Div. of Epidemiology & Disease Control, *4210 E. 11th Ave., Denver, Colorado* 80216

The aim is to study the effects of low level gamma and alpha radiation (radon and radon progeny) upon lymphocyte cytogenetics and sputum cytology among 150 long-term residents of Grand Junction, Colorado, compared to 150 long-term residents of Greeley, Colorado. Construction of homes, schools, etc. in Grand Junction from 1957 until 1966, using uranium mill tailings, exposed many persons to radiation signficantly above background level. Greeley is a control city where mill tailings are not used in construction.

CERVICAL CANCER IN YUGOSLAVIA

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201

Evidence has accumulated suggesting that prior infection with genital herpesviruses may increase risk of developing cervical cancer. This hypothesis was tested by a case-control study in Yugoslavia. (A companion study involving comparisons between 104 carcinoma in situ patients and controls is nearing completion.) An equal number of controls matching the cases in age and nationality were selected. The women were questioned intensively on their sexual, marital and pregnancy histories. In addition, illnesses and hospitalizations were reviewed and a complete gynecological examination including colposcopy was conducted, with two aliquots of blood taken for virological studies. The presence of antibodies to genital herpesviruses was then determined by means of a microneutralization procedure. Analysis continues.

FIBROCYSTIC BREAST DISEASE - EPIDEMIOLOGY AND HISTOLOGY

J.L. Kelsey, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510

This case-control study will examine the relationship beween use of oral contraceptives as well as other possible risk factors and fibrocystic breast disease, a suspected precancerous lesion, catagorized histopathologically according to extent of epithelial atypia and according to the classification system of Haagensen. Cases will be women who have had fibrocystic breast disease diagnosed from biopsy at four large Connecticut hospitals over a 22-month period. Controls will comprise women admitted as inpatients or outpatients to certain surgical services of these same hospitals. Information on oral contraceptive use, demographic characteristics, and other variables of interest will be obtained from cases and controls by means of structured questionnaire administered by trained interviewers, supplemented by queries at physicians. Previous use of oral contraceptives and exposure to other factors of interest will be compared among groups classified histopathologically as well as between each of the case groups and the controls.

BREAST CANCER IN YOUNG WOMEN - REPRODUCTIVE RISK FACTORS INFLUENCING INCIDENCE AND PROGNOSIS

D.T. Janerich, State Bureau of Cancer Control, *Empire State Plaza, Tower Bldg. Rm. 565, Albany, New York* 12237

This is a case-control, record linkage study of 318 women 25-44 years of age diagnosed with breast cancer from 1970-1976 and of 630 matched controls. Information on their reproductive histories is being obtained by linking their case records in the cancer registry with the birth certificates of their children born in New York State. Controls were selected from the birth records and matched to the cases by date of birth of first child and age of mother and county of residence at birth of their first child. Reproductive factors influencing the incidence of breast cancer in young women and prognosis are being studied. A paper entitled 'Sex of first child as a prognostic factor for breast cancer in young women' is in press.

CASE-CONTROL STUDY OF LUNG CANCER AND DIETARY VITAMIN A IN HAWAII

M.W. Hinds, University of Hawaii System, Manoa Campus, Cancer Center of Hawaii, Epidemiology Program, *1997 East West Rd., Honolulu, Hawaii* 96822

Over a period of 3 years, 500 lung cancer patients and 1,000 age and sex-matched neighborhood controls will be interviewed. Men and women of Caucasian, Japanese, Chinese, Filipino and Hawaiian/part-Hawaiian ethnic groups will be included. Trained interviewers will administer a questionnaire in the homes of cases and controls. The questionnaire will include both frequency and quantitative information on approximately 75 dietary items as well as smoking and occupational histories. The dietary items have been chosen to account for at least 85 percent of vitamin A intake for each ethnic group based on previously collected 3-day diet records. The object of the study will be to test the hypothesis of a negative relationship between lung cancer risk and dietary vitamin A.

ANACONDA SMELTER STUDY

I.T. Higgins, University of Michigan, Ann Arbor Campus, School of Public Health, Dept. of Epidemiology Environmental & Industrial Health, *Ann Arbor, Michigan* 48104

In 1969 a study of 8,047 men working at a copper smelter was published by the National Cancer Inst. (NCI). An excess of respiratory cancer related to occupational exposures to arsenic trioxide was demonstrated. There was also some indication that exposures to sulphur dioxide were related to the excess respiratory cancer mortality. The University of Michigan will study a random sample of 1,800 men originally invetigated by NCI. The arsenic exposure, work histories and vital status of these men will be updated to 1977. In addition, information on smoking habits will be obtained retrospectively. Standardized mortality ratios will be calculated based on exposures to arsenic, sulphur dioxide, and cigarette smoking.

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF PHOSPHATE WORKERS

R. Herrick, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

NIOSH is conducting an epidemiological study of mortality patterns among phosphate (fertilizer) production workers. Interest in the chronic health effects associated with this industry developed because of three observed cases of lung cancer in phosphate production workers, all reported to be non-smokers. The hypothesis of an association between lung cancer and phosphate exposure seems to be supported by studies by other Federal agencies and the Florida State Department of Health, which have suggested an increased rate of lung cancer among the county populations surrounding the phosphate plants. This study involves: (1) industrial hygiene evaluations at a number of phosphate mining and phosphate fertilizer plants, (2) a retrospective cohort

study of phosphate fertilizer workers' mortality patterns, and (3) a case-control study on the same population in the cohort study to determine if the risk of lung cancer is associated with employment in specific job categories. The facility chosen for study currently employs over 500 people, and has employed approximately 4,000 people since the start up of plant operations in 1951. The overall industrial hygiene report will be finalized in 1980. At that time it will be determined if any additional industrial hygiene monitoring is needed. Follow-up will continue for cohort study members until the vital status of approximately 95 percent has beed determined. When this is accomplished, analyses can be done for the retrospective study and cases and controls can be chosen for the subsequent epidemiological study.

IMMUNE REGULATION AND GENETICS OF DISSEMINATED NEUROFIBROMATOSIS AND ITS MALIGNANT CONVERSION

L. Helson, Memorial Sloan Kettering Cancer Center, Dept. of Pediatrics, *1275 York Ave., New York, New York* 10021

The incidence of neurofibromatosis and the factors leading to malignant conversion within those affected remain obscure. This prospective study aims to assess the genetic and immunological patterns associated with conversion to malignancy and any environmental factors which may contribute to it. Approximately 300 families from the eastern portion of the U.S. will be studied. Personal records of birth, work history, mortality, location, occupational exposures, and specific genetic factors (HLA types), fibroblast conversion, and immunological factors (immune complexes) associated with malignant transformation will be included in the analyses. The control group will be family members without neurofibromatosis. A National Neurofibromatosis Foundation has been started and ultimately may be used to contribute families.

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO TETRAETHYL LEAD

M. Haring, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Preliminary epidemiological investigation of employees of one company involved in the production of tetraethyl lead (TEL) has revealed three cases of multiple myeloma, two living and one deceased. These cases represent approximately a 30-fold excess over expectation. More comprehensive case ascertainment is proposed to locate other deaths and living diagnosed cases in the same workforce. This will be accomplished by expanding an on-going retrospective cohort mortality study conducted by the company and mailing questionnaires to former and current employees. Dependent on the results of more extensive case finding, it is proposed to screen the population for asymptomatic multiple myeloma. The cost of laboratory tests might range from 40 to 70 dollars per person. The industrial hygiene portion of this project will include both preliminary and in-depth characterization of the work environment in the TEL production areas: personal and area monitoring for TEL, the reactants in the production process, and other additives used in the blending operations.

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO DYES

M. Haring, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

In response to concern about the carcinogenicity of chemical components of oxidative and 'coal tar' hair dyes, the possibility of investigating the mortality experience of cosmetologists has been reviewed; an extensive review of records from state licensing bureaus and national cosmetologist organizations found the available data inadequate to conduct a comprehensive epidemiological or industrial hygiene study of cosmetologists as an occupational group. Another occupational group exposed to oxidative dyes includes animal fur dyers, who have been using phenylenediamine (used as an intermediate in hair dyes) in their dyeing processes since the turn of the century. Therefore, the Industry-wide Studies Branch has undertaken jointly with the National Cancer Inst. a retrospective cohort mortality study of fur dyers in the New York City area. The records of the Joint Board of the Fur, Leather and Machinists Workers' Union (FLM) have been chosen as the principal data source. Due to the restricted nature of the records, the study was limited to retirees (pensioners) on whom the most complete documentation was kept. Follow-up for the cohort is continuing, mainly through the Social Security Administration. A second union, local 3 of the Fur Floor Workers' Union, has been contacted for possible inclusion in the study. This is an excellent data source for a mortality study of all workers including active, terminated and retirees. Their data on retirees could be used to supplement those of the FLM due to the similarities in ethnic background, geographical location of the shops and jobs performed.

MORTALITY STUDY IN A LARGE CHEMICAL PLANT

G.M. Marsh, University of Pittsburgh, Graduate School of Public Health, Dept. of Biostatistics, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260

This is a historical-prospective study of the long-term health effects of employment in a large chemical producing plant. The objective is to determine the cause-specific mortality experience of workers exposed to a myriad of chemicals, for periods up to 50 years after first exposure and relate this to duration and type of exposure. Expected numbers of deaths will be computed based on the white male general populations of the US, the State of Massachusetts, and the counties from which the workforce is largely drawn. A cohort has been developed of 2,490 wage earners who worked one or more years between 1 January 1949 and 31 December 1966. The vital statistics of this cohort will be determined as of 31 December 1976.

3.2454,

POPULATION-BASED STUDY OF LOWER URINARY TRACT TUMORS

L.D. Marrett, Connecticut Cancer Epidemiology Unit, Dept. of Epidemiology & Public Health, *30 College St., New Haven, Connecticut* 06510

The aim is to gain further knowledge of the etiology and epidemiology of bladder tumors (BT) and, more especially, of other lower urinary tract tumors (LUTT) in the State of Connecticut. In particular, the importance of the well documented risk factors for BT in Connecticut and whether passive smoking, common skin exposures, or analgesic abuse are also risk factors, the level of risk, and whether the etiology of LUTT is the same as that of BT will be studied. As part of a national study, data on a large number of suspected risk factors for bladder cancer have been collected by home interview on all new cases of lower urinary tract tumor diagnosed during 1978 in Connecticut residents aged 21-84 at diagnosis and on a random sample of the Connecticut population of the same sex-age distribution as BT cases. Interviews including information on smoking, occupational and industrial exposures, artificial sweetener and coffee consumption, hair dye use, quality of drinking water, passive smoking, and skin exposures to a variety of industrial and household materials have been completed on 415 BT cases, 26 cases of LUTT, and 881 controls. During the next two years additional cases of LUTT diagnosed in Connecticut will be ascertained using the statewide reporting system which supports the Connecticut Tumor Registry (CTR) to identify cases and the CTR to provide tumor data, giving a total of about 100-110 patients. Cases will be interviewed using the same questionnaire with additional questions on use of analgesics. In addition, a sample of the controls and BT cases and all non-bladder lower urinary tract tumor cases already interviewed will be interviewed again about their use of analgesics.

ENDOMETRIAL CARCINOMA - COMPARISON OF OLMSTED COUNTY AND MAYO CLINIC REFERRAL PATIENTS

G.D. Malkasian, Mayo Clinic, Dept. of Obstetrics & Gynecology, *200 1st St. S.W., Rochester, Minnesota* 55901

The 1,191 patients who had their initial treatment for endometrial carcinoma at the Mayo Clinic between 1952 and 1972 have been identified. In addition, 12 patients who were residents of Olmsted County, but had their initial treatment elsewhere have also been identified. The purpose of this study is to compare the characteristics of the patients by residence. Residence classifications are: Olmsted County, Minnesota; the remainder of the eight counties in Southeast Minnesota; the remainder of the 100-mile radius from Rochester; other Minnesota/Iowa/Wisconsin residents; other US residents; and, finally, foreign residents. The effect of residence status will be determined on the following variables: age; stage and grade; other prior malignancies, particularly breast cancer; prior diabetes; parity; obesity; prior exogenous estrogen use; and survival (to be corrected by stage and grade). The purpose of this investigation is to determine to what extent referral patterns alter the characteristics of endometrial carcinoma patients seen at the Mayo Clinic as compared to those characteristics in the total ascertainment system for Olmsted County, Minnesota.

CHANGES IN LUNG CANCER INCIDENCE ASSOCIATED WITH SOCIO-ECONOMIC, DEMOGRAPHIC, AND SMOKING FACTORS AMONG CUBAN IMMIGRANTS (ABBREV)

C.J. Lynch, Enviro Control Inc., Smoking & Health Program, *11300 Rockville Pike, 1 Central Plaza, Rockville, Maryland* 20852

This is a case-control study of the effects that changes in socio-economic, demographic, and smoking factors have on the incidence of lung cancer among Cuban immigrants to the United States who now reside in the Miami/Dade County area of Florida. A detailed questionnaire is administered to lung cancer patients in several hospitals in the Miami/Dade County area, and to two matched controls: one a patient hospitalized for other than a tobacco-related illness; the other a non-hospitalized subject living in the same residential neighborhood as the case. The questionnaire contains detailed questions on smoking habits and more general questions on occupation, education, alcohol consumption, dietary and related factors. Data from this study will be compared to data obtained from a companion study being conducted in the Havana, Cuba metropolitan area by the IARC under sponsorship of the National Cancer Institute's Smoking and Health Program. The comparison is intended to identify factors associated with reported changes in lung cancer incidence among the population under study.

LOW DOSE RADIATION AND LEUKEMIA

A. Linos, Mayo Clinic, Dept. of Medical Statistics & Epidemiology, *200 1st St. S.W., Rochester, Minnesota* 55901

All diagnosed cases of leukemia in Olmsted County residents between 1955 and 1974 (a total of 138 cases) have been identified. Each has been appropriately matched with two controls. Cases and controls are being compared with regard to their exposures to radiation for therapeutic, diagnostic, and other reasons. The effect of a life-long experience of low-level radiation (less than 300 rads to the bone marrow) on the development of leukemia is being investigated.

INFLUENCE OF OCCUPATIONAL AND ENVIRONMENTAL ASBESTOS EXPOSURE ON MESOTHELIOMA INCIDENCE IN CONNECTICUT

H.C. Lewinsohn, Raybestos-Manhatten Inc., *100 Oakview Dr., Trumbull, Connecticut* 06611

It has been reported, using Connecticut Tumor Registry (CTR) data, that the incidence of mesothelioma in Connecticut has exhibited a sizeable increase since 1935. A positive correlation with the State's total asbestos consumption and the results of an air monitoring program for asbestos concentrations in Connecticut have served to justify a more stringent ambient air standard for the State. The present study has been designed to re-examine the CTR identified cases with respect to: (1) quality of diagnosis, and (2) direct and indirect domestic and occupational asbestos exposure. Medical, demographic, and occupational data have been collected for 229 cases of malignant mesothelioma, 38 cases of non-mesothelioma pleural tumors, their respective spouses, and approximately 700 decedents from the Division of Health Statistics of the Connecticut Department of Health. Sources of information include the records of the CTR, death certificates, city directories, as well as computer linkage programs with the files of the Connecticut Motor Vehicle Department and with the files of Connecticut decedents. An asbestos product listing with its associated employer and industrial codes has been developed to indicate possible occupational asbestos exposure. A slide review is underway in order to examine the quality of diagnosis.

INDUSTRIAL INCIDENCE OF BRAIN TUMORS

S. Leffingwell, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

In response to an alleged excess of brain tumors among employees at a plant in Texas an investigation was launched in November 1978. Preliminary data from the company, local unions, and local physicians and surgeons show ten cases where death certificates indicated brain tumor as cause of death. One additional living employee was found to have a brain tumor. The cell types were predominantly glioma or glioblastoma multiforme, with one 'meningioma, angioblastic (sarcoma).' The work force at the plant presently numbers 2,500. Between 7,500 and 10,000 workers worked in the plant from 1941 (when the plant began operation) to the present. The present aim is to seek further cases, confirm cases by pathological review of tissues, to carry out a proportional mortality study (as a check of methodology which may be useful elsewhere), a case-control study of brain tumor deaths and a cohort mortality study. Coding of company records is being completed and the case-control study will begin soon.

RELATIONSHIP OF PESTICIDE USE AND CANCER MORTALITY IN RURAL CALIFORNIA

J.F. Kraus, University of California, Davis Campus, School of Medicine, Dept. of Community Health, *Davis, California* 95616

The purpose of this descriptive epidemiological study is to assess the relationship between pesticide use in rural California counties and excess cancer mortality. Twenty years of Californian cancer mortality data will be analyzed with extant information on pesticide application, including amount, type, frequency of application, acreage of application, crop, etc. Mortality data from 1960-1977 have been obtained from the State Department of Health Services, Vital Statistics Unit. Analysis will focus on standardized mortality ratios for all causes or for specific site causes.

FDA/NCI STUDY OF THE ROLE OF SACCHARIN IN BLADDER CANCER OF THE GENERAL POPULATION

A.S. Narayana, University of Iowa, University of Iowa Hospitals & Clinics, Dept. of Urology, *500 Newton Rd., Iowa City, Iowa* 52242

Following reports suggesting that two artificial sweeteners initiate or promote bladder cancer in animals, cyclamates were banned in the U.S. in 1969, and saccharin was removed from the list of substances 'generally regarded as safe' in 1972. Howe et al. (1977) reported the first positive association between bladder cancer in humans and artificial sweeteners. At present there is not enough evidence to confirm the hypothesis that use of artificial sweeteners increases the risk of bladder cancer in human beings. The study is a collaborative effort of the National Cancer Inst. and nine other areas, and the data pooled consist of information on almost 3,000 newly diagnosed bladder cancer patients over a twelve-month period. All patients between the ages of 21 and 84 years were included in the study, and were interviewed in their homes by specially trained interviewers who also interviewed two age- and sex-matched controls for each case. The number of controls interviewed is approximately 6,000. All the data have been submitted to the National Cancer Inst. for analysis. Samples were used which were large enough to detect even a modest elevation of risk. In addition, the study is based upon a population composed of diverse subgroups, which may distinguish between initiation and promotion of cancer.

REPRODUCTION IN CANCER PATIENTS

J.J. Mulvihill, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Clinical Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (02138)

Fertility and reproductive history in cancer patients, especially in long-term survivors of childhood cancer, and in men and women who reproduced during cancer therapy are being documented to study possible mutagenicity and teratogenicity of cancer treatments, and to discover hereditary patterns of cancer. Current phases include (1) interviews of 2,500 adults who survived cancer in childhood and up to 5,000 sibs as controls; (2) recall of U.S. National Cancer Inst. patients for detailed examinations of offspring; and, (3) case collection through correspondence with physicians in co-operative clinical trial groups.

3.2466,

TWO-STAGE MODEL FOR CARCINOGENESIS

S. Moolgavkar, Inst. for Cancer Research, Fox Chase Cancer Center, *7701 Burholme Ave., Philadelphia, Pennsylvania* 19111

It is well known that cancers of specific sites have characteristic age-specific incidence curves. It is believed that this is a reflection on the population level of fundamental biological processes underlying carcinogenesis, and has led to the search for pathogenetic models which could explain this fact. A model which views carcinogenesis as the end result of two discrete and specific events at the cellular level has been proposed. The incidence curves generated by the model describe the qualitative features of the age-specific incidence of both childhood and adult cancers. The model provides a natural framework for the understanding of human cancers that occur in both hereditary and non-hereditary forms, and for the interpretation of data from animal experiments. In the present study a test of this model against epidemiological data will be undertaken. A preliminary analysis shows that the model fits the age-specific incidence curve of breast cancer in females extremely well (tested against data from Connecticut, Denmark, Iceland, Finland, and Osaka). In addition, it provides natural interpretations of the various epidemiological features of the disease. The model will be tested against the data for breast cancer in females, bronchogenic carcinoma of the large bowel and malignant melanoma.

AGE-EFFECTS AND TEMPORAL TRENDS IN CANCER

S. Moolgavkar, Inst. for Cancer Research, Fox Chase Cancer Center, *7701 Burholme Ave., Philadelphia, Pennsylvania* 19111 (02056)

Multifactorial analysis of cancer incidence and mortality data can shed light on the dynamics of temporal evolution of the disease, and permits the extraction of statistically adjusted age-specific incidence curves that are free of the distorting effects of tem-

poral trends thus increasing the precision with which pathogenetic models for carcinogenesis can be tested against incidence data. In the present study a multifactorial analysis of incidence and mortality data for cancer of the bronchus, bladder, pancreas and the large bowel, and malignant melanoma will be made. Data will be obtained from various populations, and analyzed to study the relative importance of early and late environments on the temporal trends in these cancers. Good data on cigarette smoking are available in the U.K. and U.S.A. This information will be incorporated into the analyses to study the association between cigarette smoking and carcinomas of the lung, bladder, and pancreas in these countries. It will then be possible to adjust for the effects of cigarette smoking in these diseases in order to study more subtle trends. The statistically adjusted age-specific incidence curves will be used to test a two-stage model for carcinogenesis in a separate study.

CASE-CONTROL STUDY OF LUNG CANCER MORTALITY AMONG FOUNDRY WORKERS

B.A. Miller, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Environmental Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205

The study is a matched triple (2 controls per case) case-control design. There are 113 cases of lung cancer (ICDA 162.1, 8th Revision) and 226 controls, classified as dying from causes other than cancer, making a total study population of 339 subjects. This population is restricted to white males, and matching of cases and controls was based on dates of birth and death. Employment histories are now being sought for these individuals to determine the type of foundry worked in (e.g., iron, steel, brass), specific job titles and employment dates. The general objective is to attempt to identify associations between the lung cancer deaths and a particular foundry type and job title. Since the variables measured do not represent specific exposures to chemical agents, it is the purpose of this study only to suggest possible high risk lung cancer situations in the foundry which might then require further investigation to delineate the substances responsible.

CASE-CONTROL STUDY OF BREAST CANCER

L.J. Melton, Mayo Clinic, Dept. of Medical Statistics & Epidemiology, *200 1st St. S.W., Rochester, Minnesota* 55901

This is a case-control study of the 303 incident cases of breast cancer diagnosed among Olmsted County, Minnesota, women in the ten year period 1965-1974. For each case, a control woman of the same age and race was selected from among all Mayo Clinic registrations for local residents. The control pool consists primarily of outpatients and represents a very large population in this age range. Data on traditional breast cancer risk factors will be collected, but the emphasis of this study is estimation of the odds-ratios associated with the use of various therapeutic hormones, including conjugated estrogens.

COHORT STUDY OF COLO-RECTAL POLYPS AND SUBSEQUENT CANCER

R.J. Spencer, Mayo Clinic, Dept. of Colon & Rectal Surgery, *200 1st St. S.W., Rochester, Minnesota* 55901

In order to examine the theory that polyps are premalignant tumors the incidence of colo-rectal polyps in Rochester will be determined using the population-based epidemiological data resource of the Rochester Program Project, from which all residents with a colo-rectal polyp diagnosed in the period 1960-1969 can be identified. The incidence of new polyps and the development of cancer of the colon and rectum will be determined in approximately 500 patients with diminutive polyps and some 250 patients with a larger number of polyps. Age-specific rates of colorectal cancer for the Rochester population will be applied to the person-years of follow-up to determine if there is an increase in cancer in this group of individuals.

PROSPECTIVE STUDY OF PERSONALITY AND RISK OF CANCER

R.B. Shekelle, Rush Presbyterian St. Lukes Medical Center, Dept. of Preventive Medicine, *1753 W. Congress Pkwy., Professional Bldg. 907, Chicago, Illinois* 60612

The Western Electric Health Study began as a prospective epidemiological investigation of coronary heart disease in 1958 with the examination of 2,107 male employees aged 40-55 years. The Minnesota Multiphasic Personality Inventory (MMPI) was included in the 1958 examination, the Cattell 16 Personality Factor Questionnaire in the 1959 examination, a social factors questionnaire in 1960, and the MMPI again in 1962. Questionnaires from participants or next-of-kin and death certificates will be used in 1978-1979 to identify possible incident cases of cancer; medical and hospital records will be reviewed for information about diagnosis, treatment, and course of the disease. A total of 246 incident cases are expected. Two separate hypotheses will be investigated: (1) that psychological depression, as measured by the D scale in the 1958 MMPI, is associated with increased 20-year risk of cancer, and (2) that characteristic use of denial and repression as assessed by Welsh's Factor R in the 1958 MMPI, is similarly related to increased risk of cancer. In addition, item analysis and discriminant analysis will be used to search for other aspects of personality that may be related to cancer occurrence. Factors such as age, smoking habits, consumption of alcohol, and educational attainment will be taken into account. Analyses will be conducted for all cases of cancer together and, where numbers are adequate, for site-specific categories. The results of this study will help to establish whether previous findings concerning the association of psychological factors and cancer were artifacts of the retrospective method or whether these previous findings, in fact, represent premorbid psychological characteristics of persons who develop cancer.

3.2473,

CANCER RISK AFTER IRRADIATION AND/OR CHEMOTHERAPY

D. Schottenfeld, Memorial Sloan Kettering Cancer Center, Dept. of Medicine, *1275 York Ave., New York, New York* 10021

The primary objective is to determine whether Hodgkin's disease patients are at increased risk of developing multiple primaries following varying doses and/or ordered sequences of radiation therapy and chemotherapy (given singly or in combined regimes). Histopathological classification of Hodgkin's disease and the extent of disease at first treatment will be studied in relation to the patterns of second primary cancer occurrence by organ site and histopathology. Quantitative estimation of radiation exposure will consider the total dose of radiation delivered, the energy used, the volume of tissue irradiated and the fractionation pattern of the treatment. Multiple entry and exit life tables will be used to characterize temporal patterns of exposure to different treatments, either alone or in combination. Patients will be withdrawn as transfers (not losses) from one treatment classification to another according to interval following first treatment. Internal historical cohorts of patients having received different doses and combinations of therapy will be identified and followed longitudinally to contrast their subsequent multiple primary cancer experience. Risk of new primary cancer among 1,500 Hodgkin's disease patients who have been intensively treated with potentially carcinogenic drugs, such as alkylating agents and steroid hormones, should identify carcinogenic doses or treatment combinations.

CASE-CONTROL STUDY OF IMMUNOBLASTIC LYMPHADENOPATHY AND HISTIOCYTIC LYMPHOMA

R. Ross, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033

Lukes and Collins have suggested a new clasification of non-Hodgkin lymphomas based on morphology and function of the cell type involved, thus providing a meaningful basis for epidemiological study of lymphomas. Recently a distinctive pathological lesion denoted lymphoid tissue-immunoblastic lymphadenopathy (IBL) or angioblastic lymphadenopathy (ABL) has been identified. Although not a malignant process, the clinical course is often rapidly progressive with death resulting from infection. In some patients a true malignancy ensues, an immunoblastic sarcoma, or histiocytic lymphoma by the Rappaport Classification. Follow-up of patients with IBL and/or histiocytic lymphomas questioning them about initial onset of symptoms, antecedent environmental exposures relative to occupation, medications, and residence may elucidate etiological agents involved, and a family history may provide answers to a genetic predisposition. Laboratory studies include immunoperoxidase labeling and immunoglobulin levels. Controls are matched for age, race, sex and socio-economic status. The study has been extended to include all non-Hodgkin lymphomas cases for 1979 and 1980.

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF SHIPYARD WORKERS EXPOSED TO RADIATION

R. Rinsky, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

In a proportional mortality study conducted by Drs Najarian and Colton, a significant increase in deaths due to neoplasms of lymphatic and hematopoietic tissues was reported among shipyard nuclear propulsion workers. The results of their study indicated that exposure to radiation at levels previously thought to be safe may be unsafe. The NIOSH subsequently initiated a retrospective cohort mortality study. As part of the study, approximately 27,000 civilian employees have been identified as having worked at this naval shipyard since 1954. To date, more than 3,000 deaths have been identified among the study population. The vital status will be determined for the remaining identified study population and death certificates retreived and verified. Results of in-depth industrial hygiene and health physics surveys will be related to current and past occupational and chemical exposure to chemical and physical agents other than radiation. An exposure history will be compiled and assigned to appropriate job titles/locations.

MORTALITY STUDY OF HIGH NICKEL ALLOY WORKERS

C.K. Redmond, University of Pittsburgh, Graduate School of Public Health, Dept. of Biostatistics, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260

There is evidence of increased incidence of respiratory cancers, including cancers of the nasal sinuses, among workers in the nickel refining industry. In order to determine whether any such relationship might exist among workers in the high nickel alloy (more than 20% Ni) industry, cause-specific mortality and especially site-specific cancer mortality among workers in eleven study plants across the USA will be investigated. The mortality experience of nickel-exposed workers in the study plants will be compared to the population of workers involved in all phases of operation in the study plants, and to the total United States mortality experience. The study is a historical prospective follow-up on a cohort of approximately 20,000 workers with at least one year of job experience during the period 1956-1960. The work will involve developing a coding system for classifying jobs to permit comparisons across plants with similar occupational groups and follow-up procedures for former workers to determine vital status for all individuals in the cohort.

EPIDEMIOLOGY OF MALIGNANT MELANOMA

B.S. Pasternack, New York University, School of Medicine, Dept. of Environmental Medicine, *100 Washington Sq. E., New York, New York* 10003

A number of factors have been previously reported to be associated with high risk of malignant melanoma. These include age, sex, race, ethnic origin, complexion, ability to tan, hair color. eye color and sun exposure. A case-control study has been designed to determine the degree of association between the occurrence of malignant melanoma and possible risk factors, including some which have not received quantitative analysis previously. The total data base will consist of approximately 1,100 cases and a similar number of controls. Cases are being drawn from the tumor registry of the NYU Skin and Cancer Unit, whereas controls are randomly selected from the NYU Skin and Cancer Unit patients without melanoma or other neoplastic conditions. It is hoped that this study will lead to the identification of high risk groups at whom future monitoring for malignant melanoma could be directed. Significant positive associations found in the study, if corroborated by others, may also identify behavior patterns which, if modified, could result in a decreased incidence of the disease.

LIPID LEVELS AND CHOLESTEROL METABOLISM IN RELATION TO HUMAN BREAST CANCER RISK

A.E. Papatestas, Mount Sinai Medical Center, Dept. of Surgery, *1 Gustave L. Levy Pl., New York, New York* 10029

The role of lipids is being explored to evaluate whether dietary or metabolic factors affect causal mechanisms for the development of breast cancer, systemically, or locally at the target organ. Controls are matched to cases by age, race and menopausal status. Data on past medical and family history, dietary habits, lipid levels and cholesterol metabolism in patients with breast cancer and in controls (patients and volunteers) are analyzed. Correlations between these parameters and epidemiological risk factors, or tumor characteristics are examined. Data on tissue emzymes, fat cell size and hormone receptors are examined for correlations with lipid levels. Results to date show that cholesterol differences were striking in low breast cancer risk ethnic groups. In hyperlipidemic women relative breast cancer risk was 11.0 (ratio of discordant pairs) significant using McNemar's test: 8.33, p smaller than 0.005. The combination of 'increased' weight and 'high' cholesterol appeared to be associated with rapid tumor growth. Among 348 cases, 167 (48%) had Stage I tumors while the rest had more advanced tumors. The corresponding figures for women in whom both weight and cholesterol values were above the group mean was 31/83 (37%) while for their counterparts it was 136/265 (51%). The differences between the groups were significant (chi square is 4.94, p smaller 0.05).

HEALTH EFFECTS OF THE PETROCHEMICAL INDUSTRY

E.R. Glazer, State Epidemiological Studies Lab., *2151 Berkeley Way, Berkeley, California* 94704

The refining, transportation and secondary processing of petroleum generates certain compounds known to be carcinogenic or otherwise hazardous to human health. The objective of this project is to assess the long term health effect of the petrochemical industry on workers in the industry and on the surrounding community. The initial phase of the project is being performed in Contra Costa County, California, which has four large petroleum refineries and numerous chemical plants concentrated along its northern border. Among the studies being done is a correlational analysis of measures of petrochemical emissions and health outcomes such as cancer incidence. A case-control study of childhood cancer is being planned. This will explore the relationship between parental exposure to petrochemical and the development of cancer in children and young people between the ages of 0 and 24.

MORTALITY, MEDICAL AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO PCBS

A. Smith, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Polychlorinated biphenyls (PCBs) are a class of chlorinated aromatic hydrocarbons widespread in the environment, highly stable, and tending to bioconcentrate in the food chain. Current use is primarily limited to closed systems in the electrical industry as insulating material in capacitors and transformers. Reports of adverse health effects in humans and animals accidently exposed to PCBs, and the demonstration of carcinogenic effects in certain animals from certain PCBs necessitate evaluation of the toxicology of these compounds. In laboratory animals, structural function changes in the liver have been noted as well as hepatic tumor induction in certain species; in humans, the syndromes of chloracne, and Yusho neonatorum have been extensively documented, in addition to gastrointestinal, endocrinological, hematological, and embryotoxic effects. A determination of the health effects from exposure to PCBs is being assessed by (1) a retrospective mortality study of a cohort of occupationally exposed workers; (2) a cross-sectional medical survey of a cohort of currently employed workers; (3) a detailed industrial hygiene survey. The mortality study is well under way; follow-up is near completion on the two study cohorts exposed to PCBs. The medical surveys have been completed and data analysis is in progress. The industrial hygiene surveys on all plants included in the mortality study and medical study have been completed.

CANCER AND DRINKING WATER QUALITY IN NORTH CAROLINA

R.J. Struba, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514

In this study 3,000 cancer cases and an equal number of frequency matched non-cancer controls were compared on several aspects of drinking water quality. Sites examined were colon, rectum and bladder; matching criteria were age, race, sex and geophysical region. Data sources were state mortality, and state and regional water supply statistics. The water systems were characterized on the basis of source, type of chlorination, and presence of upstream pollution (previous use) for the 1960 time period. Urban residence, occupation and socio-economic status are also being controlled in the analysis. Preliminary results show small and significant odds ratios for all three sites (especially bladder and rectum) for treatment, source, and previous use.

3.2484,

MORTALITY, MEDICAL AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO TOLUENE

F. Stern, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Recently toluene has received much attention for its potential long term health effect due to occupational exposure. The Toxic Substance Control Act has listed toluene for further study, and the Chemical Industry Inst. for Toxicology has listed it as a first priority for study. Toluene is a chemical of major use in U.S. industry today. In 1970, it was estimated that 694 million gallons of toluene were produced and approximately 100,000 workers were potentially exposed. In addition, it is expected that toluene will be substituted for benzene in many industrial processes. Investigators have noted the acute toxic properties of toluene which include effects on the nervous system, liver, blood cells and chromosome changes. Of specific interest, exposed workers have exhibited depressed erythrocytes, macrocytosis, hepatomegaly, and chromosome breaks and aberrations. Chromosome changes have also been noted in exposed rats. The current federal standard is 200 ppm as an 8-hour TWA with an acceptable ceiling level of 300 ppm and acceptable maximum peaks above the ceiling of 550 ppm are allowed for 10 minute durations. However, controlled exposure of human subjects to 200 ppm for 8 hours produced mild fatigue, weakness, confusion, lacrimation, and paraesthesias. Since chronic exposures may cause damaging effects, NIOSH has recommened a limit of 100 ppm (TWA) with a ceiling of 200 ppm for a 10 minute sampling period. This project will involve a retrospective cohort mortality analysis of an occupational population to determine whether or not there are any long term chronic health effects from toluene exposure. The first phase will be a feasibility study to determine extent of exposure, to characterize the work environment, and to assess the feasibility of conducting the mortality protion of the study. A plan for a cross-sectional medical study is also being proposed.

3.2485,
MORTALITY AND INDUSTRIAL HYGIENE STUDY OF LEATHER INDUSTRY WORKERS

F. Stern, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

Several case-control studies have indicated that individuals employed in the leather industry may experience an excess risk of developing bladder cancer. In an attempt to gain further insight into the relationship between bladder cancer and the leather and leather products industry, mortality rates for bladder cancer were examined in those U.S. counties where the leather industry comprises at least 5% of the total employment of the county. Twenty-four counties in six states met these criteria. A definite pattern of increased bladder cancer was found in the 'leather counties' in New England and New York State; however, no unusual risks were found in the 'leather counties' of Pennsylvaina and Tennessee. It should be noted that the leather industry in Pennsylvania and Tennessee consisted mostly of small-scale operations of the shoemaker-repairer trade, whereas the leather industry in New York and England was mainly leather tanneries. Leathermakers are potentially exposed to chromates, benzidine-based azo dyes and numerous other suspect carcinogens. In addition, NIOSH has recently detected environmental levels of dimethylnitrosamine which has been demonstrated to be an extremely potent carcinogen in numerous animal studies, in a leather tannery. A cohort mortality/industrial hygiene study will be conducted to further evaluate these excess risk data. The first phase will be a feasibility study to determine extent of exposure, to characterize the work environment and to assess the feasibility of conducting the mortality portion of the study.

3.2486,
GENETIC EPIDEMIOLOGY OF BREAST CANCER IN FAMILIES

M. King, University of California, Berkeley Campus, School of Public Health, Dept. of Biomedical & Environmental Health Sciences, *Berkeley, California* 94720 (02275)

The objective of the study is to determine the genetic, cultural, and environmental factors that cause breast cancer in cluster in some families. Large, extended families with high incidence of breast cancer are investigated using tools from genetic analysis and epidemiology. The existence of possible susceptibility alleles, greatly increasing cancer risk in women of the high-risk genotypes, is tested by searching for clinically innocuous marker genes that may 'track' the inheritance of the susceptibility gene within a specific family. The existence of gene linked to GPT (probably on chromosome 10), which increases susceptibility to breast and ovarian cancer in some families, has been suggested by these studies. Investigation of other genetic mechanisms of inheritance of susceptibility to breast cancer is in progress. In addition, the interaction of genetic and environmental risk factors influencing breast cancer risk among female relatives in high-risk families is being studied using epidemiological techniques. The prevalence of genetically-influenced breast cancer among American Caucasian women is being estimated.

RETROSPECTIVE COHORT MORTALITY STUDY OF MINERS EXPOSED TO AMPHIBOLE MINERAL

S.D. Kaplan, S R I International, Center for Community Health Studies, *333 Ravenswood Ave., Menlo Park, California* 94025 (02326)

Cummingtonite-grunerite is an amphibole mineral present in the ore of an underground gold mine. Because non-chrysotile forms of asbestos are amphibols, two previous epidemiological studies of the mortality experience of workers in this mine have been published, but are in substantial disagreement about the risk of lung cancer in these miners. The study cohort comprises all men who worked at least a year full-time underground between 1940 and 1975 in the mine and consists of over 3,000 individuals. Vital status has been ascertained from information in the work histories supplemented by further information from mine personnel, the Social Security Administration, state motor vehicle records, state welfare records, and U.S. Government sources. Comparison of risk of death from specific causes will be accomplished by analysis through a modified life table program based on the mortality experience of the comparable U.S. population, coded cause of death information from the death certificates, and demographic information from the mine records.

EPIDEMIOLOGICAL STUDY OF OVARIAN CANCER

G.B. Hutchison, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115 (02325)

This case-control study of ovarian cancer involves 400 patients with the disease and 400 controls selected from the general population. The pathology for each case will be reviewed and classified according to specific histological type by a recognized expert in ovarian cancer pathology. Personal home interviews will be conducted to assess a variety of epidemiological factors including general medical and family history, occupation, tobacco and alcohol habits, pregnancies, breast feeding, contraceptive experience, and drug use, including intra-uterine exposure to drugs for the younger subjects. The total number of ovulatory cycles as well as the longest series of consecutive ovulatory cycles uninterrupted by pregnancy, lactation, or oral contraceptive use will be estimated and their correlation with ovarian cancer risk determined. Also of major interest are the relative risks associated with oral contraceptive and hormones for the menopause. A doubled risk of cancer associated with several of the risk factors under study will be detectable in sub-groups of ovarian cancer of 75 patients or more. The goal is to identify risk factors that may be modified to reduce disease occurrence and may be of clinical use in defining women at risk to achieve better control of the course of the disease.

3.2489,
VALUE OF SELECTED BIOMARKERS IN DEVELOPING A RISK INDEX OF ASBESTOS-RELATED DISEASE IN SHIPYARD WORKERS

H.A. Guirgis, University of California, Irvine Campus, California College of Medicine, Dept. of Community & Environmental Medicine, *Irvine, California* 92664 (02411)

The major objective is to evaluate the utility of epidemiological host factors and selected laboratory immunochemical markers in constructing an index for surveillance of malignant disease associated with environmental exposures particularly to asbestos in shipyard workers. Epidemiological data indicate that the latter are at a higher risk for several malignancies (lung, gastro-intestinal tract, other cancers and mesothelioma) than expected in the general population. The applicability of an index constructed from epidemiological risk factors (e.g. smoking, environmental exposure, age, occupational history) and immunochemical markers (e.g., CEA, mitogen activation to PHA, %T lymphocytes) will be tested in an experimental and a comparison group from the shipyard population. The experimental group will consist of shipyard workers known to have had a significant exposure to asbestos (defined as an exposure that has produced positive findings consistant with asbestosis or chest x-ray or pulmonary function tests). The comparison group (matched for age, smoking, ethnicity and amount of manual labor) will be selected from workers who do not have a history of asbestos exposure and who do not have any evidence of pulmonary or pleural disease. The epidemiological factors will be used as classification variables or will be corrected where appropriate. Each of the immunochemical tests will also be tested individually for their value in discrimination power between exposed and non-exposed subjects. The value of the results of this study will mainly be as a surveillance tool of workers exposed to asbestos: (1) to identify those at high risk (primary prevention) and/or (2) to be used for early diagnosis of asbestos related malignancies (secondary prevention).

MORTALITY STUDY OF U.S. COAST GUARD SHIPYARD WORKERS

D.J. Grauman, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., *9000 Rockville Pike, Bethesda, Maryland* 20205 (02266)

The U.S. Coast Guard is involved in the building and repair of its ships, as well as the manufacturing and painting of buoys which are used worldwide. Over the past 40 years, a major portion of the ship repair work, some shipbuilding and some of the buoy manufacturing has taken place at the Curtis Bay shipyard in Maryland. During this period, the shipyard workers were exposed to asbestos, metals including zinc chromate and lead, tributyl tin oxide and various solvents that are known or suspected human carcinogens. The purpose of this cohort follow-up study is to evaluate the mortality experience of this group of approximately 5,000 shipyard workers in light of their occupational exposures. Cause-specific mortality rates will be compared to expected rates from the local area or the general U.S. population.

CANCER MORTALITY AND OCCUPATIONAL RISK

M.S. Gottlieb, Tulane University of Louisiana, School of Medicine, Dept. of Medicine, *1430 Tulane Ave., New Orleans, Louisiana* 70112 (02464)

Several cancer sites were associated with occupational risks in a case-control death certificate study. The next-of-kin of the cancer cases and their matched control will be contacted for more specific occupational, residential, dietary and cigarette smoking patterns. The cancer cases occurred in selected Louisiana parishes from 1960-1975. High risk occupational groups will be identified and prospective studies designed to further study the associations with cancer morbidity and mortality. To identify a 2 to 3 fold relative risk in relatively common occupational exposures 200 cases and another 200 controls will be studied for each cancer site/occupational exposure under consideration.

3.2492,
EPIDEMIOLOGICAL-ENVIRONMENTAL STUDY OF WOOD DUST

J.F. Gamble, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Epidemiological Investigations Branch, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (02239)

Approximately 2,000 workers in different phases of the wood products industry will be examined for the acute and chronic effect of exposure. The examination will include before- and after-shift pulmonary function testing, with concurrent environmental measurements and questionnaire on symptoms. Non-exposed workers from the same plants as the exposed and workers from the same region but not in the wood industry will serve as controls. A mortality study will also be conducted using a cohort of workers from the same plants. The purpose is to determine the prevalence of symptoms and reduced pulmonary function in workers exposed to wood dust, estimate dose-response relationship between morbidity and exposure, and evaluate the mortality experience of workers exposed to wood dust using the SMR.

TEMPLATE-COMPUTER PROGRAM FOR COLLECTION, EDITING AND ANALYSIS OF CANCER PATIENT DATA

G. Everett, University of Texas, University of Texas System Cancer Center, M.D. Anderson Hospital & Tumor Inst., Dept. of Epidemiology, *6723 Bertner Ave., c/o Texas Medical Ctr., Houston, Texas* 77030 (02493)

The objective of this study is to develop a streamlined computerized approach to facilitate the collection, editing and analysis of data for clinical studies of cancer patients. This 'program that writes programs' needs only the list of data items in order to produce code sheets, an edit program, and an analysis program tailored for a particular study. This design eliminates the need for individual programming at each step of the study. The system is adaptable to a wide variety of studies and is particularly appropriate for consultant epidemiologists and biostatisticians who routinely work with a number of investigators. The system is complemented by programs which keep a patient data base, presently 150,000 records, current. These include generation of follow-up dates, production of follow-up letters and matching with extramural files in state health departments, such as patient deaths and retrospective studies. Methods to continually update files are being developed as are systems to provide automatic replies to the large number of enquiries sent to the tumor registry.

REVIEW OF THE EFFECTS OF ARTIFICIAL SWEETENERS ON BLADDER CANCER

N.A. Dreyer, Equifax Inc., Health Systems Division, *100 Main St., Reading, Massachusetts* 01867 (02368)

Data from a nationwide study of artificial sweeteners and bladder cancer are being re-evaluated to learn whether any reasonable hypotheses of association raised in previous animal and human studies are supported by a recent National Cancer Institute study of 8,800 people. The following hypotheses will be considered: (1) artificial sweeteners are weak 'primary' carcinogens, which in humans act independently of the effects of sex, smoking and occupational exposures; (2) Artificial sweeteners are incomplete carcinogens, which produce human bladder cancer only in conjunction with certain other conditions or exposure; (3) Artificial sweeteners increase an individual's risk for bladder cancer by a constant multiplier, no matter what the individual's 'baseline' may be; (4) In addition, the risk of bladder cancer is monotonically related to the intensity and duration of artificial sweetener use. This analysis is intended to provide regulatory authorities and others with information on which to base their decisions regarding the safety of artificial sweetener use.

EPIDEMIOLOGY OF LEUKEMIA IN RURAL IOWA

K.J. Donham, University of Iowa, Inst. of Agricultural Medicine & Environmental Health, Dept. of Preventive Medicine & Environmental Health, *Oakdale Campus, Oakdale, Iowa* 52319 (00157)

Unlike most cancers, leukemias occur at elevated rates in rural and farm populations. Previous studies have been unsuccessful in identifying any specific risk factors for leukemia in rural areas or farming. Using incidence data from the Iowa State Health Registry, extensive preliminary ecological epidemiological studies have been completed which indicate that there are elevated leukemia rates in Iowa which are strongly associated with: (1) males, (2) rural residence, (3) proximity to high cattle population densities, and (4) proximity to dairy herds with cases of bovine lymphosarcoma. The elevated rates and the associations were primarily associated with acute lymphoid leukemia (ALL). This is a case-control study to verify the ecological relationships seen in the preliminary studies, and to investigate on an individual basis the role of various factors in the rural and agricultural environment that may contribute to the observed high leukemia rates. Approximately 200 cases of ALL (male and female) will be drawn from the Iowa State Health Registry, for the 87 most rural counties in the state. Two normal controls for each case will be selected from the same counties, and cases and controls will be matched for age, sex, and county of residence. Personal interviews will obtain data on: (1) environmental or occupational exposure to cattle, (2) environmental or occupational exposure to Bovine Leukemia Virus (BLV), (3) farm or non-farm occupation, (4) various exposures within farming such as agricultural chemicals and other livestock species. Dairy herds of cases and controls will be tested serologically to determine the extent of BLV infection. The data will be analyzed to discern a possible cause-effect relationship of exposure to cattle, BLV, and other factors in the rural/agricultural environment.

THE AMERICAN FAMILY LIFE STUDIES

E.S. Delzell, Duke University, School of Medicine, Dept. of Community & Family Medicine, *Box 3711, Durham, North Carolina* 27710 (01821)

The American Family Life Assurance Company, a national cancer insurance company, has made its records available for epidemiological research. It currently has 2.7 million policies in force, approximately two thirds of which are family policies. Pathological reports to confirm diagnoses of cancer and detailed descriptions of treatment received are required for receipt of benefits or reimbursement. All this information is microfilmed. A series of studies will be based on these records. The first will be the determination of age- and sex-specific cancer incidence rates in the insured population to serve as the reference rates in the other studies. The second group of studies will be on the occurrence of cancer in spouse-pairs to assess the role of shared environment in the etiology of several cancers, such as Hodgkin's disease, colon, and genital and reproductive tract cancers. The third group will be on the risk of second primary cancers in relation to different types of therapy. Dose-response relationships will be evaluated for those therapies found to increase the risk of second primary cancers. Other studies will include examination of sibling aggregation in childhood cancer, re-evaluation of the 'cancer-family' hypothesis and cancer incidence rates in specific occupational groups.

NORTH-EAST FLORIDA LUNG CANCER STUDY

J.E. Davies, University of Miami, School of Medicine, Dept. of Epidemiology & Public Health, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152 (01969)

This study proposes to gather retrospective data concerning asbestos exposure on all new lung cancer cases in four north-east Florida counties. The study will consider occupational histories as well as smoking. The study will also locate geographically all cases and two matched controls to ascertain any possible clustering patterns associated with major air pollution sources in the area. Case verification has been performed by an independent pathology review and analysis is anticipated concerning morphological types of lung cancer and specific risk factors. The study is also identifying mesothelioma and asbestosis cases for the same time period (1978-79 and geographical area.

GEOGRAPHICAL ANALYSIS AND CAUSAL INFERENCE

R.K. Cleek, University of Wisconsin, Center System, Washington County Center, Dept. of Geography, *400 University Dr., West Bend, Wisconsin* 53095 (02231)

The methodology of the geographical analysis of cancers have not been fully developed. Specifically, the implications of the geographical scale of epidemiological research has not been integrated into research results and cross-scale synthesis of results has not been pursued. This study of county-level mortality data (1950-1969) within and across states in the US aims at formalizing and exemplifying the inferences that can be made by studies at specific geographical scales and by the comparison of studies at different scales and populations. The analysis utilizes multivariate correlation and regression techniques, spatial autocorrelation analysis and spectral analysis.

METHODS OF SURVEYING CARCINOGEN-EXPOSED WORKERS FOR GENOTOXICITY AND MUTAGENS IN BODY FLUIDS

B. Commoner, City University of New York, Queens College, Graduate School, *65-30 Kissena Blvd., Flushing, New York* 11367 (02259)

Workers in cohorts of less than 100 are being monitored for parameters of genotoxicity (DNA adducts, DNA damage, etc.) and for levels of mutagens in body fluids (urine). Cohorts are chosen on the basis of their known exposure to a single or single class of known carcinogens, and followed for varying periods. Objectives are to identify methods that may be useful in epidemiological studies for carcinogen/teratogen risk. Cohorts may be expanded and followed for monitoring actual cancer experience at a future time.

FARMING AS AN OCCUPATIONAL RISK FOR CANCER

L.F. Burmeister, University of Iowa, School of Medicine, Dept. of Preventive Medicine & Environmental Health, *Jessup Hall, Iowa City, Iowa* 52240 (02316)

Iowa death certificates from 1971-1978 were studied to determine if white male Iowa farmers had higher levels of cancer mortality than similar individuals in non-farming occupations. The study included 6,402 farmers and 13,809 non-farmers. The overall mortality from all cancers was significantly lower in farmers due to decreased mortality from smoking-related cancers (lung, mouth other than lip, esophagus and other respiratory). However, the following cancers were significantly elevated in mortality in Iowa farmers: lip, stomach, prostate, lymphoid tissue, leukemia, multiple myeloma.

EPIDEMIOLOGY OF PRIMARY LIVER CANCER IN SELECTED TEXAS COUNTIES

P.A. Buffler, University of Texas, Health Science Center at Houston, School of Public Health, Dept. of Epidemiology, *6515 Freeman, Houston, Texas* 77025 (02490)

Several counties in Texas have been identified as having high rates of primary liver cancer (PLC), approximately three times as great as that reported for the total USA. Three of these counties are associated with heavy chemical and petrochemical industry concentrations. During 1977-1980, a retrospective study of all liver cancer deaths occurring in Brazoria, Jefferson and Orange Counties, Texas during the interval 1946 - 1976 was conducted to determine if the proportion of chemical and petrochemical workers is higher among persons dying from PLC than among persons dying from non-malignant diseases. Occupational histories were obtained from participating industries for liver, pancreas, kidney and selected other cancer deaths and controls. Clinical and histopathological review of all deaths due to PLC and other liver-related diseases was conducted. Initial findings indicate that the proportion of chemical workers dying from liver cancer was not greater than the proportion of employed controls. The clinical and histopathological review of reported liver cancer deaths indicate substantial misclassification of metastatic tumors. Of the 176 reported cases, 54 were confirmed PLC and 75 were found to be metastatic tumors. Analysis of the job classification of employed workers is continuing in 1981.

EPIDEMIOLOGICAL AND INDUSTRIAL HYGIENE INVESTIGATION OF A URANIUM ENRICHMENT PLANT

D.P. Brown, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Biometry Section, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (02315)

In recent years concern has increased over the possible adverse health effects from exposure to low-level radiation, including alpha radiation. However, few epidemiological studies have examined potential risks in terms of mortality among individuals with documented long-term exposures. The uranium enrichment plant located in Ohio enriches uranium from 0.7% U-235 to 98% U-235. Primary exposure to internal alpha radiation is from possible inhalation or ingestion of uranium hexafluoride (UF6). Over 7,000 workers have been employed at GAC since operation began in 1954. Extensive records are available to identify all active and inactive employees along with their employment history at the plant. Records on radiation exposures including monthly urinalysis results, in-vivo scanning, film badge readings and industrial hygiene measurements, are also available. These, while of limited value for assigning personal radiation dose estimates, can be used to divide the study population into categories of exposure. A retrospective cohort mortality study will be conducted by NIOSH to determine whether or not the worker population at the plant has experienced any increase in cause-specific mortality. This analysis will be done by sub-groups according to exposure and can be supplemented by more detailed analyses using a case-control approach. NIOSH will also conduct detailed industrial hygiene surveys on specific areas of the plant to characterize all relevant occupational exposures including radiation.

LONG-TERM MORTALITY STUDY OF WORKERS IN THE FURNITURE MANUFACTURING INDUSTRY

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Occupational Studies Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (02362)

The manufacture of furniture may result in worker exposure to a variety of potentially hazardous substances including wood, metal, and plastic dusts; paints, lacquers, varnishes, and stains; solvents; formaldehyde; oils, and chromium, nickel, and cadmium fumes. To evaluate the cancer risks among workers in this industry a cohort of 10,000 to 15,000 furniture workers who were members of a Union 15 to 30 years ago will be assembled and traced to determine their present day vital status. Mortality patterns among the cohort will be compared to the experience of U.S. general population after appropriate adjustments for differences in age, race, and sex. Occupational exposures will be estimated using job titles, products manufactured, and any environmental measurements currently available. The data of first employment and years of employment will be used to establish the timing and duration of exposure.

REPRODUCTIVE EFFECTS OF PATERNAL AND MATERNAL EXPOSURE TO RADIOACTIVE URANIUM WASTE ON THE NAVAJO RESERVATION

H.R. Bertell, Ministry of Concern for Public Health, Dept. of Health Research, *151 East St., Buffalo, New York* 14207 (02508)

The purpose is to investigate the role of (1) paternal occupational exposure to radiation in the mining and/or milling of uranium bearing ore, and/or (2) paternal and/or maternal environmental residential exposure to radiation from uranium mine waste or mill tailings in the etiology of birth anomalies, childhood cancer and leukemia in the Shiprock, New Mexico area. A case-control study will match nearest normal births to index cases, defined as all congenital anomalies, all stillbirths, all births with a head circumference measurement in the lowest 5% of all resident births as well as cancer cases. Exposure to various potential radiation sources will be ascertained by careful review of occupational, residential, and school attendance histories of parents of all cases and controls. This information will be corroborated by government records and reports. A computer program designed for case-control study of environmental exposure will be analyse the data. In the event of positive findings, the results will be used to assist in instigation or acceleration of remedial action so as to minimize future exposure. The size of the study population is 34,000. There are about 700 live births per year. All births between 1964 and 1979, about 10,000, will be included.

CLASSIFICATION AND ETIOLOGY OF CHILDHOOD BRAIN TUMORS

D.F. Austin, State Dept. of Health Services, Resource for Cancer Epidemiology Section, *1450 Broadway, Oakland, California* 94612 (02515)

In California, malignant tumors are the second leading cause of death among children under 15 years of age. Tumors of the brain and spinal cord are in second place among neoplasms. The aim is to reclassify selected brain tumors in children, to compare the new classification with survival and to develop some etiological factors associated with these new tumor sub-types. This five year national study will be carried out on a collaborative basis by eight SEER areas, including the Resource for Cancer Epidemiology, and Children's Hospital Medical Center, Boston. The specific aims are: (1) the evaluation of clustering among histological and clinical features of selected and clinical features and clusters, (2) to search for temporal and geographical differences in the occurrence of site-specific tumors, (3) to carry out a case-control epidemiological study of site-specific childhood brain tumors in an attempt to identify risk factors, (4) to create a computer-based program based on these data which might assist accurate prognosis. Interviews with the natural parents of each case will be arranged, appropriate comparison families selected and interviewed, medical data abstracted from hospital charts, tissue slides obtained from hospitals, and length of survival of each case monitored.

3.2509,

HISTOLOGICAL TYPE OF LUNG CANCER AND SCAR LUNG CANCER IN ASBESTOS

O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Senior Medical investigator's Lab, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (01516)

It has been noted that the histological type (WHO) of lung cancer which develops under conditions of exposure to specific environmental (occupational) hazards appears to be related to the extent involved. Oat cell carcinoma (WHO type 2) has been the predominant type found among uranium workers and a high proportion of oat cell carcinomas were also reported in chloromethyl methyl ether workers. This suggests that there may be one histological type which is predominant among asbestos workers. A previous study on scar cancer has noted its peripheral location in the lung. Some investigators have noted that lung cancer in asbestos workers tends to arise more in the periphery of the lung than in the main bronchi. If this is true, then lung cancer in asbestos workers may be associated with scars to greater degree than lung cancer in workers not so exposed. To investigate both of these hypotheses sections have been collected from surgical and autopsy specimens from large number of men who were occupationally exposed to asbestos as factory workers or asbestos insulation workers. The distribution of the histological types of lung cancer found on these slides will be compared to lung cancer cases in which there has been no asbestos exposure. Smoking, occupational and residence histories will be obtained from families of the deceased.

CHEMICAL EXPOSURE STUDIES IN FLORIDA COUNTIES WITH UNUSUALLY HIGH CANCER PREVALENCES

T.E. Aldrich, University of Miami, School of Medicine, Dept. of Epidemiology & Public Health, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152 (02336)

Florida counties having higher than expected occurrences of selected types of cancer (and possible oter health effects) will be identified. Field epidemiological methods, including environmental sampling chemical exposure assessment, will be used to study human exposure to chemicals via drinking water contamination. Specific investigations have been proposed; the first to deal with trihalomethanes and melanoma and cancer of the brain, bladder and pancreas. Other studies proposed include exposures related to Agent Orange, pediatric cancer risks and

toxic waste disposal sites. The preliminary study group is expected to involve 100 cases and 100 age, race, sex and life-style matched controls.

Description provided by IARC and DKFZ with ICRDB/NCI support.

EPIDEMIOLOGICAL STUDY OF CANCERS OF THE LYMPHATIC AND HAEMATOPOIETIC SYSTEM, GENITO-URINARY SYSTEM, SKIN AND NERVOUS SYSTEM (TRUNCATED)

D.M. Winn, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Environmental Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (02402)

The purpose of this case-control study is to identify jobs within the U.S. Coast Guard (CG) which may be related to the occurrence of selected cancers among CG officers and enlisted persons. Cases include between 200 and 300 persons with confirmed cancers of the lymphatic and hematopoietic system, genito-urinary system, skin, and nervous system who applied for a disability retirement from the CG between 1954 and the present. Confirmation of the cancer will be from medical documentation submitted to the CG medical board supporting the individual's request for a disability pension. Controls will include CG workers with none of the cancers of interest who are matched on age, race, sex, and enlisted/officer status to the cases. Additionally, enlisted controls will be matched on year of entrance into the CG: officers will be matched on attained rank. Information will be obtained from personnel records regarding the dates and duties involved for each occupational title held by a study subject both prior to and during his years at the Coast Guard. Controls will be obtained from card files and registers enumerating all enlisted persons and officers. The analysis will be conducted separately for each cancer site grouping; within each series, cases and controls will be compared with respect to jobs held and duration of employment in these jobs.

HEALTH STUDY OF PLUTONIUM WORKERS

G.S. Wilkinson, University of California, Central Office, U.S. Dept. of Energy Los Alamos Scientific Lab., *P.O. Box 1663, Los Alamos, New Mexico* 87545 (00347)

Current and former plutonium workers from six major United States nuclear facilities are being followed in order to ascertain incidence and mortality from cancer and other disease. Systemic plutonium body burden data, obtained from urinalyses and information concerning confounding external radiation exposures will be employed to investigate the presence or absence of dose-response relationships. A study population of approximately 2,000 individuals will include all workers with estimated body burdens that exceed one nanocurie, exposed workers with smaller or undetectable burdens, and random samples of non-exposed individuals from the same installations.

EPIDEMIOLOGICAL METHODS - U.S. URANIUM MINERS

A.S. Whittemore, Stanford University, School of Medicine, Dept. of Family Community & Preventive Medicine, *300 Pasteur Dr., Stanford, California* 94305 (02354)

The objective of the study is to re-analyze, using newly developed statistical techniques, the relationship between cigarette smoking and occupational radon daughter exposure to bronchial carcinoma among approximately 4,000 U.S. uranium miners. To date, approximately 400 bronchial carcinomas have occurred in this cohort.

3.2514,

EPIDEMIOLOGICAL STUDIES OF URANIUM MINERS AND MILL WORKERS

R.J. Waxweiler, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (00031)

Uranium miners have been found to have an excess of lung cancer and mill workers to have an excess of lymphomas. A much larger group of mill workers is now being studied by a retrospective cohort study to determine the magnitude of the lymphoma excess. Identification of the substance responsible is being attempted. Two groups of uranium miners are being studied; one of about 4,300, and a much larger one of about 15,000. These groups are being used to determine exposures - response curves, and the different factors which influence the shape of those curves, effects of exposure on the sex-ratio of offspring, the effect of age at first exposure on incidence and latent period, and the dose-rate effect.

Description provided by IARC and DKFZ with ICRDB/NCI support.

3.2515,

MORTALITY STUDY OF POTASH MINING WORKERS EXPOSED TO DIESEL FUMES

R.J. Waxweiler, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (02443)

The long term effects of diesel exposures need to be thoroughly evaluated as diesel fuel will begin to take on more important role in this country's future energy policy. An occupation believed to have high levels of diesel exposures is underground mining. Although most mines would have many other confounding exposures (such as asbestos, radon daughters and arsenic), potash mines have presumably non-carcinogenic environments as determined by a previously conducted retrospective cohort mortality study of 2,743 underground and 1,143 surface potash miners (J. Occup. Med. 15: 486-9, 1973). Diesels were introduced in these mines in the early 1950s, thus by extending the epidemiological study from 1967 to include follow-up through 1978, a 25 year latency period could be evaluated for many of the miners. In-depth industrial hygiene surveys would characterize current worker exposure to diesel exhaust and evaluate existing engineering controls and work practices. The control technology section of NIOSH has an analogous project to evaluate diesel exposure underground in relation to such parameters as duty time, preventive maintenance, etc.

3.2516,

ASBESTOS AND CANCER

M. Warnock, University of California, San Francisco Campus, School of Medicine, Dept. of Pathology, *551 Parnassus Ave., San Francisco, California* 94122 (00482)

In previous studies in this Department it was not possible to show a correlation between coated asbestos fibers (bodies) and lung or gastrointestinal cancers in persons with very little asbestos burden. Methods have now been developed for analysis of uncoated asbestos and other fibers in the lung and it has been found that total asbestos burden is not related to asbestos bodies. The aim is to examine the role of asbestos in disease by quantifying the amount and type of asbestos in lungs obtained post mortem from patients with a history of exposure to it in order to establish a dose-response relationship for asbestos and pleural plaques, lung cancer and fibrosis (asbestosis). Disease will be documented by review of the patient's clinical history and laboratory tests, and relatives will be interviewed to obtain a history of exposure. Lungs will be examined macroscopically and microscopically for degree and extent of fibrosis and type of cancer. Length and width of fibers will be measured and identified by electron diffraction and microprobe analysis. Because other types of fibers are present in the lung and have been implicated in disease in the past and may play a role in addition to asbestos, all other fibres (with aspect ratio greater than 3) will be examined in the same way in these same patients.

3.2517,

EPIDEMIOLOGICAL STUDY OF WORKERS IN PETROLEUM REFINERIES

T.L. Thomas, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Occupational Studies Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (02476)

A proportionate mortality ratio study of workers who were active and retired members of the Oil, Chemical, and Atomic Workers International Union employed by three Texas oil refineries revealed increased relative frequencies of deaths from stomach cancer, brain tumors, and leukemia. Underlying cause of death was recorded as stomach cancer for 48 workers, malignant or unspecified brain tumor for 37 workers, and leukemia for 33 workers. Three controls were selected for each case from workers at the three refineries who died from other causes. Detailed work histories will be obtained for each case and control to determine length of employment in these plants, specific job(s) held, work location(s) within the plants, and any other employment or exposure information that is available. Work histories of the cases will be compared with those of the controls to determine whether cases with the same cancer clustered within a given work area(s) in the plants.

3.2518,

EPIDEMIOLOGICAL AND HLA STUDY OF CHRONIC LYMPHOCYTIC LEUKEMIA

M. Szklo, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (02470)

The major objective of this research is to study the epidemiology of chronic lymphocytic leukemia (CLL), focussing upon possible associations with sources of chronic antigenic stimulation, occupations and familial factors. A second objective is to define possible HLA associations with CLL. To accomplish these objectives, the study will be divided into three components. In Part I all cases of CLL first diagnosed in the Baltimore Standard Metropolitan Statistical Area (SMSA) from July 1969 through June 1979 will be identified. Medical chart review of all these cases, an anticipated number of 450, and two groups of matched controls will be performed. Part II will consist of an interview study of all cases and controls, identified in Part I. For cases and controls who have died, spouse, other next-of-kin, or closest friends will be interviewed. Part III has three components. The first is a concurrent case - control study, involving chart review, interview, and HLA testing of newly diagnosed cases in the Baltimore SMSA (150 cases expected). The second part of the study will involve a three-month follow-up of the 150 cases in order to differentiate 'indolent' cases from the 'rapidly progressive': the HLA types of these two types will be compared. The third component involves interview and HLA testing of families with two or more cases of CLL, lymphproliferative diseases and/or autoimmune diseases.

EPIDEMIOLOGY OF APLASTIC ANEMIA IN METROPOLITAN BALTIMORE

M. Szklo, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (02471)

This study has been designed to explore risk factors for aplastic anemia and acute non-lymphocytic leukemia. The study will have two phases. In Phase I, temporal trends of incidence rates of these disorders will be studied, so that etiological hypotheses can be generated. In Phase II, a case - control study will be carried out. Two general kinds of etiological agents will be explored: viruses and chemicals. In addition, HLA studies will be conducted in order to allow ex-

amination of interaction between genetic and environmental factors. It is estimated that the final sample sizes will be as follows: aplastic anemia 100; acute non-lymphocytic leukemia 200. For each case, there will be two types of matched controls: individuals with non-hematological cancers and normal individuals, selected by means of random digit dialing of telephone numbers having the same exchange digits as cases. Interviews and drawing of blood samples are now starting. It is predicted that data collection will be completed by the end of 1982.

HEALTH EFFECTS FROM INGESTION OF ASBESTOS FIBERS IN A MUNICIPAL WATER SUPPLY

E.E. Sigurdson, State Dept. of Health, Disease Prevention & Control Section, *717 Delaware St. S.E., Minneapolis, Minnesota* 55440 (01138)

The study established baseline incidence of cancer of all sites in the resident population of Duluth, Minnesota (1970 population 100,078) during 1969-1971 and will continue to monitor incidence through 1981 or longer. The purpose of the study is to determine the health effect, if any, from the ingestion of asbestos (amphibole) fibers present in the city water supply during approximately 15 years. Data are collected in the same manner as the Third National Cancer Survey and compared with the Minneapolis St. Paul component of the Survey and the Surveillance, Epidemiology and End Results Program of the U.S. National Cancer Institute. Additional information will be obtained from cancer cases of selected sites and matched controls. Incidence data for gastrointestinal sites and lung will be published in Environmental Research.

URANIUM EPIDEMIOLOGY STUDY

J.M. Samet, University of New Mexico, School of Medicine, Dept. of Medicine, *University Hill N.E., Albuquerque, New Mexico* 87131 (02430)

The Grants, New Mexico, mineral belt is the largest uranium area in the U.S. Since mining began in this district, precision of radiation measurement and stringency of radiation standards have increased. This is the first study focusing on Grants area miners and on low-level radiation exposures for which only extrapolations are now available. The purpose of the study is to investigate health effects of radon daughter exposures, with emphasis on lung cancer. The study groups is comprised of 4,100 uranium miners with at least one year underground since 1957 in the Grants area mines: 1,800 began work before 1961, with mean working level months (WLM) near 40 per year; 1,300 began work in 1961-1970, with mean WLM decreasing from 40 to four per year; the rest began work in 1971 or later, with mean WLM not exceeding the current allowable four per year. The general New Mexico population, adjusted for ethnicity, will serve as comparison group.

POSSIBLE ROLE OF VITAMIN A IN UTERINE CERVICAL DYSPLASIA

S.L. Romney, Yeshiva University, Bronx Campus, Albert Einstein School of Medicine, Dept. of Gynecology & Obstetrics, *1300 Morris Park Ave., Bronx, New York* 10461 (01133)

In this study of carcinoma of the uterine cervix the primary focus is on the possible interrelationships of diet, with emphasis upon vitamin A, social environmental epidemiological factors, and the cellular changes which are detectable clinically by routine cytology and biopsy of the uterine cervix. The availability of the Papanicolaou test permits screening of large population groups and the finding of a positive or suspicious smear identifies 'women at risk'. Such women are being studied intensively in terms of (1) diet, with computer coding and scoring of nutrient values, (2) ethnic and socio-economic background and (3) personal lifestyle including educational performance as well as (4) measurements of specific blood and tissue retinol and retinoic binding proteins.

METABOLIC EPIDEMIOLOGY OF LARGE BOWEL CANCER IN A DEFINED POPULATION

B.S. Reddy, American Health Foundation Inc., Division of Nutrition, *Hammond House Rd., Valhalla, New York* 10595 (02426)

The overall objective of the proposed research, continuing an on-going comprehensive program, is to (1) acquire significant information on the mechanisms related to, and the role played by, dietary components, gut microflora and their metabolites on the etiology of large bowel cancer in humans; (2) identify specific fecal constituents that directly and/or indirectly cause large bowel cancer or promote the development of large bowel neoplasms, and (3) develop key biochemical indicators which distinguish low- and high-risk populations for large bowel cancer. The dietary profiles, fecal bile acids and fecal mutagens of 100 healthy Seventh-Day Adventists, who are at low risk for colon cancer development, and of age- and sex-matched healthy non-Seventh-Day Adventists, who are at high risk for colon cancer in the New York Metropolitan area will be studied. In addition, the effect of dietary fiber in the form of wheat bran on the excretion of fecal mutagens in the volunteers from the New York area, who exhibit a high fecal mutagenic activity will be studied. It is also aimed to study the effect of vegetarian diet in the Seventh-Day Adventists consuming a non-vegetarian mixed-Western diet on the fecal bile acids, bacterial enzymes, and mutagenic activity, and to isolate and identify the mutagens in the feces of the study population.

3.2524,

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF WORKERS IN FIRED POWER PLANTS

C. Ortmeyer, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Diseases Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (02467)

Pulmonary disease and impairment could arise in part from exposures to gases emitted during coal combustion and to coal dust when coal is burned as fuel for steam-powered electricity generating plants. Those workers who handled the asbestos sheets used to insulate steam pipes may also show evidence of health damage. NIOSH and the Tennessee Valley Authority TVA are co-operating in a study of these occupational health risks. The TVA is conducting detailed cross-sectional industrial hygiene studies of workers in selected occupations. Existing industrial hygiene data on past exposures and control methods will be reviewed in order to estimate cumulative working lifetime exposures in occupations where there has been exposure to the same particulates or gases. This information will be used to attempt dose assessment for mortality studies of workers exposed in the past. An epidemiological mortality study of TVA employees is also being carried out to estimate effects in terms of higher-than-expected death rates and/or early retirement due to disability involving principally cardiopulmonary disease or specified malignancies linked to earlier exposures to air contaminants in the workplace. All permanent male employees of the TVA with five or more years of employment (at least two consecutive), and employed some time between 1 January 1955 and 39 December 1972 will be included in the cohort. Demographic data (age, sex, etc.), most recent and previous addresses, detailed work-histories within TVA, and information about dates and causes of death or of early retirement will be obtained. During data collection and analysis, NIOSH will arrange for sub-categories of 'high-risk' employees and matched non-exposed controls to be selected when analyzing the mortality data, for collection of additional diagnostic evidence regarding chronic cardiopulmonary diseases and completion of data on non-occupational exposures such as cigarette smoking, area of residence or traffic pollutants.

EPIDEMIOLOGICAL STUDY OF CHILDHOOD GLIOMAS

P. Nasca, State Bureau of Cancer Control, *Empire State Plaza, Tower Bldg. Rm. 565, Albany, New York* 12237 (02388)

The general objective is to determine, by means of an epidemiological case-control study, the importance of various prenatal and childhood environmental exposures in the etiology of childhood gliomas. Special emphasis will be placed on prenatal and early childhood exposures to drugs, chemicals, radiation, tobacco, immunizations and animals. Selected birth characteristics including maternal age, parity and season of birth will also be examined. Approximately 400 patients with childhood gliomas should be available for study, with two controls for each case. This number should permit investigation of the study variables with respect to the more common histological subtypes. Demographic, pathological and clinical data will be collected from the hospital records of each patient, utilizing a standardized form. Further data will be collected through telephone interviews with the mothers of each patient and control. These will be validated by comparing the mothers' responses with physician and hospital records.

LUNG CANCER SCREENING OF WORKERS AT HIGH RISK

C. Mittman, City of Hope Medical Center, *1500 E. Duarte Rd., Duarte, California* 91010 (02387)

The overall objective is to determine if strategies can be developed to predict and/or prevent lung and bladder cancers in steel workers exposed to the coke oven environment known to increase risk. This is a five year prospective study of approximately 6500 coke oven workers in 11 geographical locations in the United Statec. Sputum, urine and blood samples are collected along with lung spirometry and questionnaire data. No control group is necessary since exposure is categorized by work site and the outcome is cancer. Occupational exposure data will be used for all analyses.

HEREDITY AND ENVIRONMENT IN THE ETIOLOGY OF CHILDHOOD CANCER

A.T. Meadows, Childrens Hospital of Philadelphia, Division of Oncology, *3400 Civic Ctr. Blvd., Philadelphia, Pennsylvania* 19104 (02386)

A case - control study of risk factors for specific childhood neoplasms has been initiated which will focus on three case groups: (1) tumors of neural crest origin, including CNS tumors, retinoblastoma, and neuroblastoma; (2) lymphoreticular neoplasms, including the leukemias and lymphomas; and (3) Wilms' tumor. Three matched controls will be chosen for every case, including a sibling control, a child with a different type of cancer, and a population control chosen through a random-digit-dial telephone technique. Variables of interest in the etiology of neural crest-derived tumors include (1) drugs that affect the CNS (anticonvulsants, alcohol, phenothiazines, amphetamines, tricyclic antidepressants, benzodiazepines); (2) ionizing radiation; (3) pesticide/herbicide exposure; (4) fetal exposure to chicken pox/influenza; and (5) family history of CNS disorders, genetic disorders, or cancer. Variables of interest in the etiology of lymphoreticular neoplasms include (1) maternal or paternal occupational exposure to petrochemicals/organic solvents, or to arsenic; (2) maternal or paternal employment in the rubber, shoe, or farming industry; (3) exposure to ionizing radiation; (4) fetal exposure to chicken pox/influenza; and (5) family history of immunodeficiency disorders, autoimmune diseases, or chromosomal instability syndromes. Lastly, this study will investigate the relationship between Wilms tumor and (1) exposure to analgesics and hormones; (2) lead exposure; and (3) family history of diabetes, hypertension, and congenital anomalies.

3.2528,

PREDICTION OF LUNG CANCER RATES BY SPUTUM CYTOLOGY

T.J. Mason, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (00595)

In assessing the lung cancer risk of a worker population, it is highly desirable to have an early prediction method so that excess risk can be detected early. For new chemicals suspected of being pulmonary carcinogens, sputum cytology may reduce by half or more the time needed to determine the existence of risk, this possibly saving many lives. Several sputum samples from about 15,000 uranium workers have been collected over a period of 18 years. Using Dr. Saccomanno's classification, the samples will be analyzed to show correlation with age, tobacco smoking and radiation exposure. Persons with various grades of atypia will be followed to see how their sputum changes over the years, and to determine subsequent lung cancer mortality associated with each class of atypia (up to 18 years). Multiple correlation analyses will be done (utilizing support from NCI). These analyses will permit assessment of the use of sputum cytology as a survey tool assessing the lung cancer risk of a population before lung cancer has appeared.

CASE-CONTROL STUDIES OF ADENOCARCINOMAS OF THE SINONASAL TRACT

C.H. Lingeman, U.S. Dept. of Defense, Armed Forces Inst. of Pathology, Dept. of Environmental & Drug Induced Pathology, *c/o Walter Reed Medical Ctr., Washington, District of Columbia* 20306 (02248)

The purpose of the study is to identfy occupations or other types of environmental exposures that are associated with an excess risk of developing adenocarcinomas of the nasal cavities or sinuses. Cases will be the most recent patients whose biopsies have been submitted to AFIP for consultation. Controls will be AFIP accessions whose biopsies have been submitted to other registries than those involved with respiratory diseases, and who have diagnoses of diseases other than neoplasms. They will be matched to cases by age, sex, race, geographical location and data of diagnosis. Information about occupations and other environmental exposures to carcinogens will be obtained by means of questionnaires. It is hoped to study 100 cases and 200 controls. Information from both groups will be compared using standard statistical methods. Particular attention will be given to those occupations in which workers are exposed to wood dust or leather products because of reports of excessive of sinonasal neoplasms, particularly adenocarcinomas, in workers so exposed.

CASE-CONTROL STUDY OF MALIGNANT NEOPLASMS OF SOFT TISSUES

C.H. Lingeman, U.S. Dept. of Defense, Armed Forces Inst. of Pathology, Dept. of Environmental & Drug Induced Pathology, *c/o Walter Reed Medical Ctr., Washington, District of Columbia* 20306 (02249)

The purpose of the study is to attempt to determine whether exposure to chemicals in the environment is associated with an excessive frequency of neoplasms orginating in soft tissues. The first phase of the study will involve 200 case (patients with soft tissue neoplasms) and 800 controls (patients with non-neoplastic diseases). Cases will be the most recent AFIP accessions of patients 25 years and older with diagnoses of malignant neoplasms of soft tissues. Controls will be selected from the AFIP data base and will be matched by age, sex, race, geographical location and date of diagnosis. Information obtained from questionnaires concerning occupations and other possible sources of exposure to chemicals will be compared in the two groups using standard statistical methods. Particular attention will be given to phenoxyherbicides and related compounds because of reports of excessive soft tissue neoplasia in people with occupational exposure to these compounds.

IMMUNE REGULATION AND GENETICS OF DISSEMINATED NEUROFIBROMATOSIS

L. Helson, Memorial Sloan Kettering Cancer Center, Dept. of Pediatrics, *1275 York Ave., New York, New York* 10021 (01979)

The incidence of neurofibromatosis and the factors leading to malignant conversion within those affected remain obscure. This prospective study aims to assess the genetic and immunological patterns associated with conversion to malignancy and any environmental factors which may contribute to it. Approximately 300 families from the eastern portion of the US will be studied. Personal records of birth, work history, mortality, location, occupational exposures, and specific genetic factors (HLA types), fibroblast conversion, and immunological factors (immune complexes) associated with malignant transformation will be included in the analyses. The control group will be family members without neurofibromatosis. Preliminary results (In Vitro, 16, 8:706-714, 1980) show no unusual HLA type frequencies. Some 60% of 70 patients had abnormal levels of immune complexes compared with 20% in family controls. Fibroblast conversion with 12-0-Tetradecanoyl phorbol-13-acetate was attempted on three families but no differences were noted when compared with controls.

PANCREATIC CANCER EPIDEMIOLOGY - SOURCES OF CASE MISCLASSIFICATION

B.C. Yankaskas, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514 (02444)

Pancreatic cancer has always been difficult to diagnose, and even with improved diagnostic techniques is most often diagnosed after metastasis or at autopsy. In view of the poor diagnosis the search for risk factors and high risk populations becomes very important. Pancreatic cancer cases used in epidemiological studies come from three main sources; death certificates, hospital series, and tumour registries. The source of diagnosis may lead to misclassification. The yield from epidemiological studies will be of higher quality when cases are similar and definitely pancreatic cancer. The object is to identify the amount of misclassification that occurs, paying special attention to the type and source of histological confirmation and diagnostic evaluation for the years 1955-1979. The study will cover all cases of pancreatic cancer identified at three University hospitals in North Carolina. Cases will be identified from the hospital tumour registries and autopsy records. Information will be taken from review of the medical chart, autopsy reports, death certificates, and all diagnostic and pathology reports. For each case a comparison will be made of clinical diagnosis, autopsy diagnosis when present, and death certificate diagnosis. The misclassification identified will be related to symptoms and histological confirmation. The effect of misclassification based on sources of cases for epidemiology studies will be estimated. Some 1,000 cases and 1,500 gastric cancer charts will be reviewed to evaluate the relationship of changing diagnostic techniques as the source of pancreatic cancer misclassification.

IMMUNOGENETIC AND IMMUNOLOGICAL ASPECTS OF NASOPHARYNGEAL CARCINOMA

S.H. Chan, University of Singapore, School of Medicine, *Sepoy Lines, Singapore 3, Singapore* (00270)

The HLA profiles of 313 newly diagnosed unrelated Chinese nasopharyngeal carcinoma (NPC) patients were compared with those of 330 normal Chinese subjects and with 98 NPC patients who had survived five years. HLA-B17 and HLA-VW46 were strongly associated with increased risks of developing NPC and HLA-A11 with a decreased risk. Joint occurrences of AW19/B, B17 and A2 BW46 were associated with a higher risk than B17 or BW46 alone. The risk associated with A2 BW46 was confined to older onset patients (greater than 30 years old) were as AW19/B B17 was associated with the total group of patients but particularly marked with younger (less than 30 years old) patients. The association of B17 and poor survival was shown both in retrospective and prospective studies. On the other hand A2 B13 was associated with good prognosis. HLA-DR blank was significantly associated with an increased risk of development of NPC (RR equals 9.6) and HLA-DRW4 associated with a decreased risk (RR equals 0.24). The next phase of research is to study some of the mechanisms of these HLA associations. It is proposed to examine the immune responses to EBV in relationship to HLA patterns.

NEURAL NEOPLASMS IN THAILAND

S. Shuangshoti, Chulalongkorn University, School of Medicine, Dept. of Pathology, *Phya Thai Rd., Bangkok, Thailand*

OBJECTIVES: (1) To study relative proportions of type, age, sex and location of all neoplasms of the nervous system in Thailand, (2) to study individual types of neural neoplasms, (3) to study highly interesting or unique cases of neural neoplasms and report them separately.

SCOPE: Review of surgical specimens and postmortem materials from two large general university hospitals in Bangkok: Chulalongkorn Hospital and Siriraj Hospital. Materials from other hospitals in Bangkok and from the rest of the country, sent in for consultation, are also included.

ANALYSIS OF CAUSES OF DEATH OF VETERANS IN SOUTH AUSTRALIA AND MULTIPLE CORRELATION ANALYSIS

R.V. Southcott, Australian Dept. of Veterans Affairs, *186 Pulteney St., Adelaide, South Australia 5000, Australia*

Studies are being made on the incidence of the various causes of death among Australian veterans residing in South Australia (males only, in view of the numbers involved), over recent years, for comparison with larger Australian non-veteran male populations. It is hoped to relate such data also to the incidence of other diseases, e.g. areas of birth and service, height, weight and other data, including hair and eye color, etc.

CANCER INCIDENCE AND MORTALITY IN GREATER SAO PAULO

A.P. Mirra, Universidade de Sao Paulo, School of Public Health, Dept. of Epidemiology, *Avenida Dr. Arnaldo, 715-10 A, Sao Paulo, Sao Paulo, Brazil* (02281)

The aims are to study cancer incidence and mortality in the Greater Sao Paulo area for the period 1969-1978. The data are collected in standard files from the following sources: hospitals, clinics, homes for aged, drug control service, pathology laboratories, autopsy services and death certificates. The data received are coded and transferred to magnetic tapes. The ordering of cancer cases is made by the first and last names of the patients, and number of registration. The unit is the cancer case and not the patient, each neoplasm being registered individually.

ANIMAL CONTACTS IN YOUNGER VICTIMS OF HODGKIN'S DISEASE AND LEUKEMIA

H. Doerken, Universitat Hamburg, Medizinische Facultat, First Medical Clinic, *Martinistrasse 52, 2000 Hamburg 20, Federal Republic of Germany*

In the age-group 15-19 years 84 cases of Hodgkin's disease have been found in the State of Hamburg and Northern Germany during the last 10 years. Cases will be compared with controls with particular reference to contact with animals and the occupation of the parents. In a more rural area (Oberallageu/ Bavaria) 191 death from leukemia occurred during the period 1959-1974. Animal contacts were analysed. An unexpected risk factor was prior use of chloramphenicol. 440 deaths from leukemia in the purely urban area of Hamburg North are now being analyzed and compared with data on controls. First results confirm the rarity of clustering.

3.2548,

RADIATION EXPOSURE AND MORTALITY IN FLUORSPAR MINERS

D.T. Wigle, Canadian Dept. of National Health & Welfare, Lab. Centre for Disease Control, *Tunneys Pasture, Ottawa, Ontario, Canada* K1A 0L2

The objective of the study is to evaluate the risk of death due to lung cancer as a function of cumulative exposure to radon and radon daughters in the fluorspar mines of St. Lawrence, Newfoundland. The mortality and adaptation exposure experience of over 2,000 men employed between 1933 and 1977 will be reviewed. Fluorspar mining in St. Lawrence (population 2,078, 1956 census) began in 1933 and by the period 1952-60, lung cancer accounted for 21 of the 71 total deaths: only 0.73 lung cancer deaths were expected based on proportional mortality rates for the province (O/E equals 29). Investigation in 1959 revealed the presence in air of radon and radon daughters at levels up to 193 SWL (1 SWL equals 100 pc/l for radon and 1.3 x 10 to the 5th power MeV total potential alpha-energy per liter for daughters) in non-working, unventilated areas. The average exposure of miners was estimated to be 2.5-10 SWL. Improved ventilation and monitoring of individual exposure were started in 1960. Current studies are directed towards evaluation of control procedures and analysis of the associations between radiation exposure and mortality utilizing individual exposure data and man-years at risk.

BRITISH RUBBER MANUFACTURERS' ASSOCIATION HEALTH RESEARCH PROJECT

H.G. Parkes, British Rubber Manufactures Assn. Ltd., Occupational Health Research Unit, *Scala House, Holloway Circus, Birmingham B1 1EQ, England, United Kingdom*

The aim of this study is to examine the health records of workers in the British rubber industry and to compare their mortality experience with that of the general population. All major type companies are included, together with some associated products. The study also compares the experience of three distinct cohorts of entry to the industry - first for those who entered the study between 1946 and 1950, the second between 1951 and 1955, and the third between 1956 and 1960. Although the main aim of the study is to investigate possible excesses of cancer hazards, all causes of death are recorded and certain other groups of causes are being examined. It is hoped to be able to associate any high risk areas with the results of environmental monitoring tests that have been made in the last year or so and with such details as can be obtained of past conditions in each factory. Analysis of the results to date has shown a small, but significant, excess of malignant disease of the stomach and of the lung, particularly in recent entry cohorts. Except for the first entry cohort there is no raised incidence of bladder cancer. This is in line with the banning of the use of 2-naphthylamine in 1949. Detailed studies of the conditions of work in those areas which show an excess of malignant disease in each factory are now being made and a further follow-up of mortality records is being undertaken.

SMOKING AND CHEWING HABITS IN RELATION TO HEALTH - A PROSPECTIVE STUDY IN BOMBAY

K. Jayant, Cancer Research Inst., Epidemiology Div., *Dr. Ernest Borges Marg, c/o Tata Memorial Ctr., Bombay 400012, Maharashtra, India*

A number of retrospective studies carried out in this country have demonstrated the association of smoking and chewing habits with oral and pharyngeal cancers. Laboratory and experimental studies on bidi smoke and betel quids have also served to establish this cause-effect relationship. To see whether the results obtained in retrospective studies are sustained in prospective studies in which large populations with known habits are followed for several years for the occurrence of cancer, a limited study of this nature has been in progress, following earlier pilot studies. About 7,000 white-collar workers and 3,500 blue-collar workers over the age of 35 have been followed up for varying periods since 1969. A preliminary analysis of the data on white collar workers is being undertaken.

A STUDY OF THE USE OF TOBACCO AND ALCOHOL BY MALES AND FEMALES OF TRANSKEI

J.S. Harington, South African Inst. for Medical Research, *Hospital St., P.O. Box 1038, Johannesburg 2000, Transvaal, South Africa*

Cancer of the oesophagus occurs at very high frequency in Transkei. There is evidence that the use of commerical pipe tobacco smoked either in pipes or as hand-rolled cigarettes may be responsible, or partly responsible, for the disease. To investigate this, a field study of geographical regions having higher and lower incidence rates (than the overall rate) of oesophageal cancer in the resident population of Transkei was carried out. Nine hundred detailed questionnaires are now being analysed and results will shortly be available.

ORAL FOCAL EPITHELIAL HYPERPLASIA (ABBREV)

F. Praetorius, Kobenhavns Tandlaegehojskole, Dept. of Oral Pathology, *Universitetsparken 4, DK2100 Copenhagen OE, Denmark*

Oral focal epithelial hyperplasia is widespread among Eskimos and Amerindians, but rare among Caucasians (Europides). In Greenlanders there seems to be a direct relationship between the prevalences found and the degree of mixture of the population with Caucasians. This may be due to an influence of a genetic factor, and serological studies are, therefore, performed. Histology and electron microscopy seem to indicate a viral etiology of the disease; the size and morphology of the virus-like particles correspond to what has been described in verruca, condylomata, and in oral papillomatosis in dogs and rabbits. Pilot studies with immunofluorescence technique have shown that the patients with focal epithelial hyperplasia produce antibodies against an antigen in the affected cells. It is likely that the disease is contagious. Epidemiological studies have been performed on 3,500 persons in Greenland and on population groups of Greenlanders and Danes in Denmark. Follow-up studies are undertaken in Greenland. Electronic data analysis of the collected material is performed in collaboration with J.E. Bearman. Blood group type studies are done on saliva samples from the same persons and are performed in collaboration with Dr. H. Guertler, Copenhagen. Family studies are carried out in collaboration with Dr. R. Gessain, Paris, who is in possession of records of the entire Eskimo population of the east coast of Greenland, dating back to about 1820. Biopsies from Greenland are studied histologically and ultrastructurally; immunofluorescence studies are also carried out. The electron microscopic studies are performed in collaboration with Dr. O.Fejerskov, Arhus, Denmark. Tissue culture studies are also performed.

PRENATAL EVENTS AND CHILDHOOD CANCER

N. Munoz, Centre International de Recherche sur le Cancer, Interdisciplinary Programme & International Liaison, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France*

This programme uses material from established prospective studies to assess the role of prenatal events in the incidence of congenital malformations. The Oxford study was started in 1972; by December 1977 cohort of 18,000 had been assembled. The pregnancy records in this study contain information on illnesses during pregnancy and on exposure to drugs and chemicals; two or more antenatal serum samples and one postnatal sample were collected for each woman admitted to the study. The Hungarian study dates from 1975 and now consists of the records of 12,500 pregnant women. In this study antenatal specimens will also be available, in addition to the pregnancy records. The children born to women participating in either of these studies are being followed to identify those with congenital malformations or cancer. The occurrence of these diseases will be correlated with specific intrauterine exposures recorded in the pregnancy records, and the serum specimens and controls will be used appropriately.

FOLLOW-UP OF PATIENTS TREATED WITH CYTOTOXIC CHEMOTHERAPY AS AN ADJUVANT TO SURGERY IN CARCINOMA OF THE BRONCHUS (ABBREV)

H. Stott, Medical Research Council, Tuberculosis & Chest Disease Unit, *Fulham Rd., c/o Brompton Hospital, London SW3 6HP, England, United Kingdom*

The objectives of the study were: (1) To assess the long-term survival in patients receiving busulphan, cyclophosphamide or placebo (allocated at random) as an adjuvant to surgery for carcinoma of the bronchus; (2) to identify important prognostic factors influencing survival; (3) to investigate the incidence of 'busulphan' lung by comparing in a 'blind' study the

radiographic abnormalities in patients receiving busulphan, cyclophosphamide or placebo; (4) to investigate the incidence of leukemia (or other cancers) following long-term chemotherapy with busulphan and cyclophosphamide. Over 700 patients were admitted to the study from 23 centers in Great Britain between January 1965 and January 1968. After the removal of all visible growth at operation the patients were allocated at random to receive busulphan, cyclophosphamide or placebo for 2 years. They are being followed up until their death and at present the follow-up has continued for 7-10 years and will continue indefinitely to measure leukemic risk.

3.2565,

ASSESSMENT OF THE CARCINOGENICITY OF ISONIAZID IN PATIENTS WITH PULMONARY TUBERCULOSIS

H. Stott, Medical Research Council, Tuberculosis & Chest Disease Unit, *Fulham Rd., c/o Brompton Hospital, London SW3 6HP, England, United Kingdom*

There is evidence that isoniazid in high dosage can induce neoplasms of the lung and lymph nodes and sometimes leukaemia. This study aims to assess the carcinogenicity of isoniazid by the follow-up of nearly 4,000 adult tuberculous patients admitted to two hospitals from 1950 to 1957. Details of the dosage of isoniazid received by the patients (including the daily dosage and duration) have been reported, as well as other antituberculous drugs received, a crude estimate of exposure to ionising radiation and of the smoking history in males. Reports of deaths among the population are obtained from the Office of Population Censuses and Surveys for England and Wales (as well as from replies to routine postal questionnaires) and the mortality in these patients is compared with that expected in the general population in England and Wales of the same age, sex and occurring during the same period. The follow-up at present ranges from 16 to 23 years after entry to the study and in view of the long induction time between first exposure to a carcinogen and the development of cancer, it is being continued indefinitely.

AN INVESTIGATION INTO THE SO-CALLED PREMALIGNANT LESIONS OF THE ORAL CAVITY

C.W. Van Wyk, University of Stellenbosch, Faculty of Dentistry, Dept. of Oral Pathology, *Private Bag 11, Tygerberg 7505, Cape Province, South Africa*

The object of the study is to determine the prevalence, the anatomical distribution, the histopathology, the ultrastructure and histochemistry of the so-called premalignant oral lesions (leukoplakias) among different population groups in Cape province (Bantu, colored, white and Asian) paying due regard to habits, social circumstances and geographical distribution. Furthermore, a similar demographic study is being carried out on oral squamous carcinomas among the same people to make comparisons between the premalignant and malignant lesions possible. In addition all other oral mucosal lesions detected during the survey are recorded and their distribution plotted. Specific investigations are undertaken into the etiology of some, especially the atrophic lesions and lesions caused by viral infections.

DIFFERENTIAL MORTALITY PATTERNS BETWEEN NATIVE-BORN AUSTRALIANS AND MIGRANTS

M.G. McCall, University of Western Australia, Queen Elizabeth II Medical Centre, Dept. of Medicine, *Nedlands, W. Australia 6009, Australia*

The initial data were published following the 1966 census. The cooperation of the Commonwealth Bureau of Statistics has been obtained to continue the study and data on all deaths in Australia (1962-1971) have been collated. 1971 was the last year for which census data are available and denominators for twenty-four migrant groups with seven periods of residence have been computed. Provision has been made for the inclusion of 1976 data when they become available. The difficulty caused by the change to the ICD 8th Revision classification has been resolved and a numerator file for any given disease is available. From this, standardized mortality ratios for a wider range of malignancies and population groups can be computed and several publications are being prepared.

LUNG CANCER IN ICELAND (1931-1972)

H. Thorarinsson, Haskola Islands, Landspitalinn, Surgical Department, *Baronsstigur, Reykjavik, Iceland*

This report is a survey of lung cancer in Iceland during the period from 1931 to 1972. The age, sex and geographical distribution are recorded and a comparison made between smoking habits and histologic types of carcinoma. The operability rate and the resectability rate versus histological types as well as the immediate surgical results and five-year survival, are discussed.

The National Cancer Registry was established in 1955 and since then all the cases have come from this institution's files as well as from the files of various hospitals throughout the country. All cases of lung carcinoma diagnosed clinically and verified histologically from 1931 to 1954 were also reviewed and summarized.

The hospital records of all the patients were studied and the macroscopic descriptions of the surgically resected lungs and necropsies were reviewed. All available microscopic slides have been re-examined by one pathologist and the tumors classified histologically. Tho WHO classification has been adhered to. The surgical files and necropsy protocols of the Department of Pathology of the University of Iceland cover all the pathologic-anatomic examinations in the country from the beginning.

Lung cancer in Iceland: The incidence of carcinoma of the lung has increased over the last two decades, and there is a definite correlation with the increased sale of cigarettes, which occurred some twenty years earlier. Tobacco consumption by Icelanders increased more than a hundred-fold during the years 1910-1949. In the period 1931-1954 only 34 cases of lung cancer were recorded, whereas during the periods 1955-1964 and 1965-1972 156 and 224 cases were reported, respectively. There is a preponderance of large cell and small cell anaplastic carcinomas in this series, epidermoid carcinoma comprising only about 20 percent. Smoking habits are known for 75 percent of the patients admitted to the Department of Thoracic Surgery: 90 percent of the patients with epidermoid carcinoma had been heavy smokers (29 or more cigarettes a day) for ten or more years; 80 percent over twenty years. The corresponding figures for the other histological types are: small cell anaplastic carcinoma 77 percent; 70 percent over twenty years; adenocarcinoma 36 percent; large cell carcinoma 69 percent; 64 percent over twenty years. RESEARCH INTO OCCULT CARCINOMA OF THE THYROID GLAND IN AUTOPSY MATERIAL AND SURGICAL SPECIMENS

F. Fialho, Hospital de Clinicas Gaffree e Guinle - FEFIERJ, *Rua Marques de Abrantes #219, Apt. 302, Rio de Janeiro, Brazil*

PROGRESS: Material from over 400 autopsies has been reviewed. Our incidence has increased above the previously reported 2.7 percent, while neither exceeding the limits reported in the literature nor approaching the incidence in high risk areas (Hiroshima, etc.).

We are conducting a critical study of the last 100 thyroid specimens obtained at autopsy, in which we have included all suspect areas. So far we have found one tumor in addition to the 4 others that were previously diagnosed in that group.

Regarding surgical specimens, we are placing special emphasis on hyperplastic goiter treated with antithyroidal agents. We believe that there may exist a relationship between occult tumors and medications (propylthiouracil) when used indiscriminately or irregularly by the patient. This may occur as a result of the personality of the thyroid patient (hyperthyroid) who may be in a state of emotional crisis and may change physicians and hospitals frequently. Such changes favor variation in therapeutic schedules which may have catastrophic results in addition to resulting in errors in treatment.

In this fashion excessive and cumulative medication schemes may occur, which may in turn cause hyperplasia, changes in cellular behavior, and finally, occult carcinoma. We have had occasion to document this phenomenon in a case of functional goiter with atypical epithelium which developed into a malignant lesion after super-dosages.

Such treatment schemes actually represent in vivo experimentation in human beings.

STUDIES ON FAMILIAL GASTROINTESTINAL POLYPOSIS IN JAPAN

J. Utsunomiya, Tokyo Medical & Dental University, School of Medicine, Dept. of Surgery, *1-Chome, Yushima, Bunkyo-Ku, Tokyo 113, Tokyo, Japan*

The objective of this study is to ascertain and register family members of patients with gastrointestinal polyposis in Japan in order to control this disease and to provide information for the genetic study on cancer. Information on the subjects was collected through inquiry, from literature, autopsy records and voluntary visits; pedigrees constructed by means of reviewing the official family register record (Koseki) and the presence of polyposes among relatives was ascertained by consulting the death certificate or by communicating with family members. Currently, 427 families suffering from familial polyposis coli (FPC) including Gardner Syndrome, 127 of Peutz-Jeghers Syndrome, 193 of multiple polyps and 65 of familial colon cancer with or without polyps are registered. A survey has been completed on 306 families of FPC and based on these materials, comprehensive studies are under way including clinicopathological studies of associated changes, genetic epidemiological analysis, cytogenetic study, genetic marker study and others.

A BREAST REGISTRY IN NORTHERN ALBERTA WITH RESEARCH AND CLINICAL APPLICATIONS

P.E. Burns, Dr. W.W. Cross Cancer Inst., Dept. of Radiation Oncology, *11560 University Ave., Edmonton, Alberta, Canada* T6G 1Z2

A breast registry has been created, in northern Alberta, to study the etiology, epidemiology, diagnosis, treatment, and patient survival of malignant and benign breast disease. Approximately 500 patients (30% of the total number) with benign breast disease and 250 patients (90% of the total) with breast cancer attend the new breast clinic at the Cross Cancer Inst. each year and extensive information is obtained for the breast registry. Data from this registry are used to examine diagnostic accuracy and the effect of delay in diagnosis; to study incidence trends; to examine etiological factors including prognostic factors and treatment methods and to determine those factors related to breast cancer patient survival. Similar aspects of benign breast disease are currently being examined.

PROGNOSIS IN BRONCHIAL CARCINOMA IN A LIMITED GEOGRAPHICAL AREA IN FINLAND

E. Huhti, Oulun Yliopisto, Dept. of Medicine, *Kajaanintie 52 A, 90220 Oulu, Finland*

The true or overall prognosis quoad vitam of patients with bronchial carcinoma is difficult to assess in clinical materials, these usually being selected in one way or another. In this study, all cases of bronchial carcinoma from 1968 to 1971 have been collected from a limited geographical area. The patients are being followed up to determine the prognosis and to see which factors are associated with a good, and which with a poor prognosis. Special attention has been paid to the histopathology of the tumours which have been classified as suggested by a WHO committee. The study is prospective and the number of patients is about 441. Factors that will be analyzed, among others, include symptoms, smoking habits, previous radiological findings before diagnosis, site of tumour, findings at bronchoscopy and mediastinoscopy, and various biochemical characteristics. The TNM classification (as suggested in 1966) will be used.

CANCER MORTALITY IN SWITZERLAND BY SITE, 1969 - 1972

R.F. Gass, Universitat Bern, Dept. of Social & Preventive Medicine, *Waldheimstrasse 18, 3012 Bern, Switzerland*

The purpose of this project is to identify variables associated with high or low mortality from cancer of different sites, based on the age-adjusted rates in the 25 cantons and 183 districts of Switzerland. The analysis is based on all deaths having occurred in Switzerland from 1969 through 1972, and on the population figures from the census of December 1970. A computer program has been prepared, testing for homogeneity, linearity, normality and mortality ratios, and for their statistical significance. Demographic, socioeconomic and environmental factors are examined by multiple regression analysis. Cancers of the stomach, oesophagus and breast are of primary interest. The results permit formulation and specification of hypotheses which will require further testing.

SELECTION AND FOLLOW-UP OF HIGH-RISK GROUPS FOR BREAST CANCER IN THE ESTONIAN S.S.R.

E. Hint, Ministry of Health of the Estonian SSR, Inst. Eksper. i Klin. Medit., Dept. of Clinical Oncology, *42 Hiiu St., Tallinn 200016, Estonian S S R, Union of Soviet Soc. Republics*

Epidemiological information about risk factors for breast cancer has been obtained from 15,000 women using a special punch card. Two main groups are being followed. The first group (7,500) has been screeened by clinical examination of the breast. If disease was suspected and confirmed, conservative or surgical treatment was given and this entire group will in future have regular breast examination, lesions being treated as they are found. The second group (7,500) consists of women for whom only the epidemiological information has been collected. These women will be offered treatment on request as for the general population. On the basis of data from the Cancer Registry, the incidence of breast cancer in the general population and in both the above groups will be compared. The significance of various risk factors and genetic variables in particular and the effect of screening program will be evaluated. Taking into consideration the risk factors of most importance, a new study will be projected.

LONG-TERM CANCER MORTALITY TRENDS AMONG KRAKOW INHABITANTS IN RELATION TO DEMOGRAPHY AND ENVIRONMENT

W. Jedrychowski, Akademia Medyczna w Krakowie, Inst. of Social Medicine, Dept. of Epidemiology, *Ul. Kopernika 7, 31034 Cracow, Poland*

The spatial analysis of mortality due to malignant neoplasms in the population of Cracow will cover the ten-year period 1974-1984. The city of Cracow has over half a million inhabitants and its four districts differ in regard to degree of air pollution, smoking habits, fertility and other social and environmental factors. The aim of the study is to make a comparison between data on mortality from malignant neoplasms in the four districts. Death certificates taken from the statistical office on a monthly basis have been used in the analysis of malignant neoplasms. Cancer mortality data are analyzed according to sex, place of residence and primary site. Age-specific and age-adjusted rates are computed for the total population and for each district. So far, data covering the years 1974-1978 have been collected and are currently being analyzed. The pilot study done for the year 1974 has shown that the most frequent causes of death in Cracow by sex were lung carcinoma in men and breast carcinoma in women. The highest age-adjusted rates were in the city center where the fertility rate was low and the level of atmospheric pollution, tobacco consumption and the proportion of working-class population appeared to be high.

MORTALITY OF BRITISH COKE-OVEN WORKERS

M. Jacobsen, Inst. of Occupational Medicine, Statistics Branch, *Roxburgh Pl., Edinburgh EH8 9SU, Scotland, United Kingdom*

The objective of this investigation is to estimate death rates from cancers in general and lung cancer in particular among British coke-oven workers. A cohort of men employed in 1967 at industrial establishments involving coking operations is being studied. Men involved are or were employees of the British Steel Corporation or of a subsidiary of the National Coal Board. Analysis of a nine-year follow-up period suggests an occupationally related lung cancer hazard at some works, and that this hazard is considerably smaller than that reported among American coke workers. The study continues.

INSTITUTE OF PETROLEUM EPIDEMIOLOGICAL SURVEY

M.R. Alderson, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom*

The aim is to monitor background data in order to quantify the overall level of morbidity and mortality and examine the variation from disease in relation to broad categories of work or 'environment'. Some twenty companies in the oil industry have agreed to fund an epidemiological study through the Institute of Petroleum. Present plans are to collect data from eight refineries (three Shell, three BP, one Esso, and one Mobil); details are required about men who have been employed for at least a year from 1950 to 1975, including those who have left the industry, retired, or died. The analysis will examine mortality rates by cause (taking age, location, and type of work into account). Comparisons will be made between men doing different work within refineries, and with the mortality data for men in other industries in the same region as each refinery and in the country as a whole. Such a study can quantify the general mortality (and thus indirectly the overall level of health in the industry). Examination of material on individual diseases may identify specific issues that warrant detailed study. This study is now being extended to workers at various distribution centers for refinery products and maintenance staff at London Transport garages.

ANALYSIS OF URINES FOR NITROSAMINES FROM PATIENTS WITH BILHARZIASIS

R.M. Hicks, University of London, Middlesex Hospital Medical School, School of Pathology, *Riding House St., London W1P 7LD, England, United Kingdom*

There is a high bladder cancer incidence in Egypt, in areas irrigated by canals from the Nile, and it is always linked with endemic bilharziasis. Bilharzial patients also frequently have chronic intractable bacterial infections of the urinary bladder. Many bacteria are capable of reducing nitrate to nitrite, and then nitrosating secondary and tertiary amines to nitrosamines. Secondary amines are normally in human urine. I have suggested, therefore, that nitrosamines could be a factor in the incidence of bladder cancer in Egypt, and if it is so, the bilharziasis is a co-factor, rather than a direct carcinogen. A pilot study has been undertaken with the collaboration of IARC, in which urines from bilharzia infested patients in Cairo and surrounding districts were analyzed by gas chromatography and mass spectrometry. Many of these patients had significantly higher levels of several nitrosamine species in their urines than did uninfested Egyptian and European individuals. For comparison, urines of European patients with chronic bacterial infections of the urinary tract were analyzed in the same way. This investigation will now be extended to other areas where bilharziasis is endemic.

GENETIC ASPECTS IN RELATION TO CANCER

V. Balakrishnan, Cancer Research Inst., Epidemiology Div., *Dr. Ernest Borges Marg, c/o Tata Memorial Ctr., Bombay 400012, Maharashtra, India*

Indian society is divided into a large number of religious and linguistic communities, many of which are further subdivided into endogamous groups (castes and sub-castes). These groups not only differ in food habits, customs etc., but also restrict marriages within a group, leading to great differences in their gene pools. While some of these groups prohibit marriages between persons related up to three or four generations, some other groups have probably the highest levels of inbreeding in the world. Patients from all parts of India attend the Tata Memorial Hospital. Information collected from these patients will be used to build up cancer profiles of the endogenous groups to see whether these differ in a manner not explained by their habits and customs. Information on close consanguinity is also collected to assess the effects of inbreeding. Patients diagnosed as not suffering from cancer will be used as controls. Information on about 3,700 cancer cases and 2,300 non-cancer cases collected during 1975-1977 was analysed. Considering 42 site combinations and 12 community groups, for the few sites which had at least 100 cases, it has been found that differences in cancer profiles for the community groups can only partly be explained by differences in smoking and chewing habits which are known to be the major risk factors for these sites. No effects of inbreeding have been found. Detailed exploration of the question would require more extensive data and collection of data is continuing.

LONGITUDINAL STUDIES IN ORAL LEUKOPLAKIA

J. Banoczy, Semmelweis Orvostudomanyi Egyetem, Conservative Dentistry Clinic, *Mikszath Kalman ter 5, 1088 Budapest VIII, Hungary* (00290)

670 patients with oral leukoplakia have been under continuous control over a period from 1-30 years, with a mean observation period of 9.8 years. The points studied are: the frequency of malignant transformation, the distribution according to age, sex, localization and smoking habits, possible etiological factors and the conditions favoring malignant transformation. In the histological material of the same leukoplakia patients the frequency of histological dysplasia and cancer as well as the ultrastructural characteristics by transmission and scanning electronmicroscopy are studied in correlation with the clinical types of leukoplakia. The patients with oral leukoplakia come from the Clinic of Maxillo-Facial Surgery and Clinic of Conservative Dentistry, Semmelweis Medical University, Budapest. Part of the results has been published. (J. Maxillofac. Surg. 5(1), 69-75, 1977, J. Oral Path. 9, 41-53, 145-154, 1980).

CORRELATIONS BETWEEN MORPHOLOGY AND EPIDEMIOLOGY OF BREAST CANCER

B.G. Stenkvist, University Hospital, Dept. of Clinical Cytology, *S75014 Uppsala 14, Sweden*

Within a clearly defined area and population (four Swedish counties) 181 breast cancer cases occurred during five months. Epidemiological and morphological data were obtained from 179 of these patients and from 179 exactly age-matched population controls. The tumors were characterized by computerized cytometry of the tumor cell population and by conventional morphology, resulting in an objective atypia measure. Comparison between patients and controls showed no significant differences in age at menarche, age at first birth, age at menopause, number of children, height, obesity, or frequency of diabetes or hypertension. These results differ from most earlier reports, possibly because the controls here were selected from the whole female population instead of hospitalized patients. Breast cancer in the family and prior breast disease in the study persons were significantly higher in the patient group. Data on thyroid hormone levels suggested that altered thyroid function in the patients was probably due to a change in the peripheral conversion of thyroxin. The patients had higher serum concentrations of estrone, androstenedione and testosterone, and a lower level of sex-hormone-binding globulin. No obvious differences in the epidemiological characteristics could be discerned among different conventional morphological subgroups. The computerized cytometry value was positively correlated with biological parameters such as mitotic rate and had significantly better reproducibility than subjective systems for classification or grading. The patients have been followed up for the first thousand days post-mastectomy. A 'malignancy grade' for breast carcinomas has been developed based on image analysis and pattern recognitions. Patients with tumors over the mean value had 39% recurrences within the first thousand days of observation, patients with tumors below this mean value - 0%. This 'high-risk' index for the first thousand days of follow-up was superior to others.

ROYAL NAVAL DOCKYARDS ASBESTOSIS STUDY - MORTALITY PROJECT

C.E. Rossiter, Medical Research Council, Clinical Research Center, Division of Computing & Statistics, *Watford Rd., Harrow HA1 3UJ, England, United Kingdom*

The 6,292 men working in the Royal Naval Dockyards on Jan. 1, 1947 were followed up to the end of 1978. About 4 percent of all deaths could be related to exposure to asbestos and over half of these were mesothelioma deaths. The mortality of this group will continue to be studied because of the possible increase in the mesothelioma rate as the period since first employment in the Dockyard passes 40 years. The 40,000 men working in all four Royal Naval Dockyards in 1972/73 are also being followed to relate their mortality, including from lung cancer and mesothelioma, to history of asbestos exposure and smoking habits.

STUDY OF EPIDEMIOLOGY, SOCIOLOGY AND GENESIS OF UTERINE CERVICAL CANCER

J.E. MacGregor, University of Aberdeen, *Aberdeen AB9 1AS, Scotland, United Kingdom*

The northeast area of Scotland is an ideal area for epidemiological studies being centred round one main city, Aberdeen. It is possible to identify individual women screened no matter how many cervical smears they have, how many different clinics they attend or how often they move within the area. Already a very high percentage of women in the region have had one or more cervical smears. A fall in the incidence of the disease has occurred and is continuing. A marked fall in mortality rates has occurred. There have been no deaths of women under 35 years of age since 1973 during which time the death rates in England and Wales were rising. Studies continue, with special emphasis on the genesis of this disease in young women.

FIBER EXPOSURE, MORTALITY AND RADIOGRAPHIC CHANGES IN QUEBEC CHRYSOTILE PRODUCTION INDUSTRY

J.C. McDonald, University of London, London School of Hygiene & Tropical Medicine, T.U.C. Centenary Inst. of Occupational Health, *Keppel St., London WC1E 7HT, England, United Kingdom*

OBJECTIVES: (1) With exposure expressed in terms of fibers per ml, averaged over time, and account taken of date of birth, age first employed, duration of employment and smoking habits to determine whether exposure discriminates between (a) men who died from selected causes and others who survived to the same ages; (b) various types of radiological outcome in men aged 45-64, employed 30 years or more. If either is so, the relative risks associated with increasing average fiber concentrations will be eliminated. (2) To determine whether and in what way the subsequent experience of chrysotile asbestos workers is related to the presence or absence in past records of (a) changes observed in routine chest x-rays taken at work, (b) impaired pulmonary function and (c) respiratory symptoms. (3) (a) To determine whether there is any important difference in the chest x-ray appearances by rate and type of change between men without other occupational dust exposure who were employed at least 10 years wholly in companies mining slip fiber or in companies mining cross fiber; (b) to describe quantitatively and qualitatively the dust and fibre exposure experienced by both groups of men.

NATIONAL SURVEY OF CHILDHOOD CANCERS

L.M. Kinnier Wilson, National Survey of Childhood Cancers, Cancer Epidemiology Research Unit, *c/o Queen Elizabeth Med. Ctr., Birmingham B15 2TH, England, United Kingdom* (00858)

This long-standing retrospective survey was originally started in Oxford by Dr. A. Stewart in 1953 to study the etiology of childhood cancers. It consists of interviews with the parents of children under 16 dying of cancer or leukemia in the United Kingdom and with parents of control children matched for age, sex and district; antenatal information is confirmed by application to clinics and doctors, and the case child's medical history is followed up through general practitioner and hospital notes. Surviving children have similarly been interviewed and followed up since 1962 by means of the regional cancer registries. In the past extensive studies have been made of the relation of obstetric low-level radiation to the increased risk of the child later developing neoplasia. The effect of viral diseases during pregnancy has also been found to increase the risk, but less convincingly. Present projects include: (1) A study of the effects of the use of drugs and ultrasound during pregnancy, and of the possible relationship of these agents in the etiology of childhood cancers; (2) A study of parental occupations and their possible relationship to the etiology of childhood cancers; (3) A study of congenital defects found in children who later develop cancer or leukemia, and congenital defects in their siblings, together with a similar study of defects in matched control children and their siblings; (4) A study of second primary tumors occurring in children after cure of their initial cancer with special attention to the effect of radiation and genetics; (5) A study of cancers among siblings.

QUANTITATIVE AND STATISTICAL PROBLEMS IN CANCER EPIDEMIOLOGY

T.D. Sterling, Simon Fraser University, School of Interdisciplinary Studies, *Burnaby, British Columbia, Canada*

Evaluation of antecedents of cancer presents complex problems of design and data evaluation. Age, sex, occupation, social class and other variables interact in complex ways. Our attempt is to re-evaluate the flaws of previous studies on antecedents of cancer in order to develop better methods for study design and data analysis.

HODGKIN'S DISEASE IN WESTERN AUSTRALIA WITH SPECIAL REFERENCE TO CONTACT BETWEEN PATIENTS WITH THE DISEASE

M.L. Matthews, Cancer Council of Western Australia, Leukaemia & Allied Disorders Registry, *184 St. Georges Terr., Shenton Park, Perth, W. Australia 6000, Australia*

Previous studies have suggested that Hodgkin's disease occurs more frequently in individuals who have had contact with patients with Hodgkin's disease than in those who have not. These studies have been designed to test this hypothesis. Patients with Hodgkin's disease have been notified to the Leukemia and Allied Disorders Registry in Western Australia since 1959. Data on these patients are being used to study space - time clustering of Hodgkin's disease and the coincident occurrence of this disease in pupils and teachers at schools in Western Australia. 108 patients with Hodgkin's disease registered since 1964 and surviving to June 1976 have been matched by sex, age and area of residence with members of the general population of Western Australia. Patients and controls have been interviewed to uncover evidence of contact. Data on relatives and close associates of Hodgkin's disease patients have been collected also to determine whether any of them have developed a lymphoproliferative or myeloproliferative disorder. Data are now being analyzed.

EPIDEMIOLOGY OF LEUKEMIA AND ALLIED DISORDERS IN WESTERN AUSTRALIA

L.E. Dougan, Cancer Council of Western Australia, Leukaemia & Allied Disorders Registry, *184 St. Georges Terr., Shenton Park, Perth, W. Australia 6000, Australia*

Patients have been notified to the Leukemia and Allied Disorders Registry in Western Australia since 1959. Further registrations were made by search of hospital morbidity indices, pathology and hematology department records and death certificate scrutiny. For patients prevalent in the period 1960 to 1969 the diagnoses were confirmed or otherwise determined by a diagnostic group of pathologists and hematologists after review of clinical and pathological material. Epidemiological and clinical data have been collected for those patients with confirmed diagnoses and incidence and mortality rates have been calculated by sex, age and geographical area. Other data collected include irradiation exposure, drug ingestion, past medical history, family history, occupation, domicile, birth order, family size, parental ages, presence of other malignancy or congenital malformations, autopsy findings and death certification. Follow-up study is continuing in order to complete survival figures and data on the development of other malignancies. Since 1969 the registration of patients has continued but diagnoses are accepted without confirmation by the diagnostic group and less detailed epidemiological information is recorded. Copies of tabulations from the 1960-1969 survey are available on request.

GYNECOLOGICAL CANCER IN WESTERN AUSTRALIA WITH SPECIAL REFERENCE TO ROLE OF EXOGENOUS AND ENDOGENOUS ESTROGENS IN ENDOMETRIAL CANCER

B.K. Armstrong, University of Western Australia, Dept. of Medicine, *Nedlands, W. Australia 6009, Australia*

The study will describe trends in mortality from gynecological cancer in Western Australia between 1930 and 1974 and incidence data collected by cancer registration between 1971 and 1974. The latter data will permit study by area of residence, occupation, race and country of birth. A retrospective case-control study of the role of estrogen therapy with mainly ethinyl estradiol in the etiology of endometrial cancer is being undertaken and will include about 200 cases and 200 controls. Data on estrogen receptors, and plasma and urinary estrogen have been collected already on over 50 patients with endometrial cancer. Data will be collected also for appropriately matched controls and related to physical characteristics, obesity, diet and other factors.

INCIDENCE OF CHRONIC DISEASE AND UTILIZATION OF HEALTH SERVICES BY MIGRANTS TO WESTERN AUSTRALIA

B.K. Armstrong, University of Western Australia, Dept. of Medicine, *Nedlands, W. Australia 6009, Australia*

The statutory collection of demographic and medical information on patients discharged from all hospitals in Western Australia renders possible the study of the incidence of chronic diseases which normally require hospitalization. Preliminary analyses have shown excesses of hospital admissions for gall bladder disease, acute pancreatitis, inflammatory bowel disease, lung cancer and chronic renal disease. These and other conditions are being studied in detail to ascertain whether true differences in incidence exist among migrants or whether the excesses observed are due to differential utilization of health services.

CANCER RISK IN VEGETARIANS

R.R. Frentzel Beyme, Deutsches Krebsforschungszentrum, Institut fuer Dokumentation Information und Statistik, *Im Neuenheimer Feld 280, D6900 Heidelberg 1, Federal Republic of Germany*

Animal experiments have shown many nitrosamines to be carcinogenic. Nitrosamine precursors in human food and vegetables have been investigated and high concentrations in certan vegetables point to the possibility of a higher risk of cancer in persons consuming particular types of greens. Analytical studies together with a mortality survey of a cohort of vegetarians are being undertaken to investigate a postulated relationship between cancer incidence and dietary habits. Depending on the result of the mortality study a prospective morbidity survey will be considered and form the basis of a case-control study. Comparison groups will be comprised of individuals having chosen a so-called 'reformed' lifestyle (i.e. preference of a natural diet, but not exclusively vegetarian) and mortality rates for both study and comparison groups will be compared with those for the general population.

EPIDEMIOLOGY AND CLUSTERS OF TUMORS IN CHILDHOOD, FREQUENCY AND GEOGRAPHICAL DISTRIBUTION

O. Bilek, Inst. of Pediatric Research, *Cernopolni 9, Brno 66262, Czechoslovakia*

OBJECTIVES: In 1960-1968, 104 cases of childhood leukemia were observed in South Moravia. A significant clustering in space (0-12 km distance) and time (0-1, 0-2 years) was found (Blut, 21, 180-185, 1970). We intend to continue this study as these population groups, which could be regarded as genetic isolates, are very suitable for comparative studies of genetic factors. The main object of the study will be: (1) To register all cases of childhood leukemia from 1969 onwards; (2) to compare the previous (1960-1968) and the new (1969-1980) results; (3) to study the families with malignancy genealogically; and (4) to study the influence of environmental factors on the incidence of leukemia, if any.

STUDIES AIMED TOWARDS FACILITATING LESS HARMFUL SMOKING HABITS

W.F. Forbes, University of Waterloo, Faculty of Mathematics, *University Ave. W., Waterloo, Ontario, Canada* N2L 3G1 (D-IARC-79-114)

Cigarette smoking is known to represent one of the main risk factors for lung cancer, and is also important in the aetiology of a number of other diseases. The objectives of the present study include: (1) the study of regional variations of various smoking-related and other diseases; (2) the undertaking of various surveys and the analyses of survey data, both in school age and in adult populations to estimate the prevalence of smoking habits in Canadian populations; (3) the study of individual smokers to determine their ability to adjust to a less hazardous cigarette (i.e., one delivering less tar, nicotine and carbon monoxide); (4) the analysis of cigarette consumption and sales data to estimate the effect of price on consumption, and to study the relationship between advertising, sales, and tar content for Canadian cigarettes; and (6) the collection of autopsy material from smokers and non-smokers, in order to investigate differences in trace-metal levels between smokers and non-smokers (particularly for cadmium and lead), and to evaluate the importance of cadmium and lead in human disease processes.

ETIOLOGY AND PREVENTION OF ORAL LEUKOPLAKIAS AND THEIR MALIGNANT TRANSFORMATION

J.J. Pindborg, Kobenhavns Tandlaegehojskole, Dept. of Oral Pathology, *Universitetsparken 4, DK2100 Copenhagen OE, Denmark*

Oral leukoplakia is well-known as a precancerous condition. On this assumption the aim of the present study has been to analyze prospectively the aetiology and pathogenesis of oral leukoplakias as well as the aetiology and pathogenesis of carcinomas developing in such leukoplakias. In this context availability of means of early diagnosis of oral carcinoma is important. By October 1978 the study comprised 750 persons who had all had a biopsy taken at the first examination. Follow-up biopsies have been performed in case of morphological changes of the lesions. Over the years the annual follow-up for each year has covered 95.6% of the persons with only small variations from one year to another.

EPIDEMIOLOGY OF CANCER IN CANADIAN HUTTERITES

K. Morgan, University of Alberta, Dept. of Genetics, *Edmonton, Alberta, Canada* T6G 2E1

Hutterites are members of a genetically isolated Christian sect who live in approximately 240 farming colonies in the Canadian Prairie Provinces and United States border states. In 1971 there were approximately 13,000 Hutterites living in the Prairie Provinces of Alberta, Saskatchewan, and Manitoba comprising over 70 percent of North American Hutterite colonies. Three major subdivisions of the Hutterites, the Dariusleut, Lehrerleut, and Schmiedeleut are distributed as follows: both Dariusleut and Lehrerleut in Alberta and Saskatchewan, and only Schmiedeleut in Manitoba. Over 200 Hutterite cases of cancer were ascertained from the three population-based provincial registries by a search of surnames for the period 1951-76. Approximately half of these cases were diagnosed in Alberta and most of the remainder in Manitoba. Comparative analyses of cancer incidence will be undertaken with respect to geography and the three major endogamous subdivisions of the Hutterite population. Preliminary results for this data set corroborate the patterns of both high- and low-risk sites determined for Alberta Hutterites.

COLLABORATIVE EPIDEMIOLOGICAL STUDY ON THE FEASIBILITY OF PREVENTING COLONIC AND RECTAL CANCERS

F.M. Martin, Universite de Dijon, Faculte de Medecine, Dept. of Immunology, *7 Blvd. Jeanne d'Arc, Dijon, France* 21000

Colonic and rectal cancers represent a major cause of cancer mortality in France. They seem to result, in most cases, from transformation of precancerous lesions - intestinal polyps. The survey aims at evaluating the exact frequency of colonic and rectal polyps in gastroenterology clinic population, assessing the value of examinations used for their detection (double contrast enema, fiberoptic endoscopy, assessing the prevalence of polyps and cancers in the study population, determing the effect of routine excision of polyps on the incidence of colorectal cancers. For this, eight medical or surgical centers register patients or asymptomatic individuals, among whom routine screening of colorectal tumors are carried out. This study was activated on January 1977; by November 1978, 1,242 cases had been registered.

FEASIBILITY STUDY OF BREAST CANCER SCREENING

A.B. Miller, National Cancer Inst. of Canada, Epidemiology Unit, *77 Bloor St. W., Toronto, Ontario, Canada* M5S 2V7

A project is being initiated in Toronto with the collaboration of the College of Family Physicians of Canada and the Women's College Hospital of Toronto to evaluate the feasibility of the procedures planned for a national study of breast cancer screening in Canada. Approximately twelve family physicians will be invited to identify women aged 40 to 64 in their practice, from whom data on identifying information and risk factors for breast cancer will be collected by means of a self-administered questionnaire. These women will then be assessed by the physician for their stability for participation in the study in which approximately half the women would be chosen at random to (1) be invited to attend the Women's College Hospital for a breast cancer screening examination including mammography and clinical examination by a nurse, or (2) to remain under the care of the family physician without such referral. All women participating in this study will be taught breast self-examination. Informed consent to the transfer of the questionnaire to the National Cancer Institute of Canada, Epidemiology Unit, and to randomization will be obtained. In six month period approximately 1,000 women will be screened. Additional data on dietary and other variables will be obtained from those attending the screening center. It is anticipated that this will be the first stage of a study which will eventually be carried out across Canada and which will involve the recruitment and randomization of approximately 100,000 women aged 40 to 59.

DIET AND BOWEL CANCER

A.B. Miller, University of Toronto, *Medical Sciences Bldg., Toronto, Ontario, Canada* M5S 1A8

The study has been designed to investigate the role of diet in the causation of bowel cancer. A high intake of protein, fat and refined carbohydrates and a low intake of fibre have all been associated with high incidence of large bowel cancer. This is a case-control study to be conducted in two geographically distinct areas of Canada -Metropolitan Toronto and Calgary. In both areas an unselected series of newly diagnosed patients with bowel cancer will be admitted to the study. Data from such patients will be compared against age- and sex-matched neighbourhood and frequency-matched hospital controls.

EXOGENOUS ESTROGENS AND THE DEVELOPMENT OF CANCER OF BREAST AND ENDOMETRIUM

R.W. Morgan, University of Toronto, Faculty of Medicine, Dept. of Preventive Medicine & Biostatistics, *92 College St., Toronto, Ontario, Canada* M5S 1A8

This retrospective cohort study is designed to examine the risk of breast cancer and endometrial cancer in menopausal and postmenopausal women who had received estrogen therapy for other than contraceptive purposes. The study group is composed of 1,678 women (ages 40-55) in Toronto, who, between 1960 and 1970, were started on long-term estrogen therapy for menopause (Cohort A). Drug use information and epidemiological data are being obtained from the following sources: gynecologists' records, Ontario Cancer Registry, Ontario Cancer Foundation, and telephone interviews. The incidence rates for breast cancer and endometrial cancer will be compared with age-specific incidence and mortality rates of the female population of Ontario (Cohort B). The mortality rates for the study population will also be compared with age-specific cancer mortality rates of the Canadian female population (Cohort C). An estimate will be made of the relative and attributable risk of developing malignant breast disease or endometrial carcinoma and of dose-response relationships of oestrogens to disease.

RETINOBLASTOMA IN FINLAND SINCE 1912 - INCIDENCE OF OTHER MALIGNANT NEOPLASMS IN RETINOBLASTOMA PATIENTS AND THEIR RELATIVES

A. Tarkkanen, Helsingin Yliopisto, Eye Hospital, *Haartmaninkatu 4, 00290 Helsinki 29, Finland*

It has been suggested that retinoblastoma might be used as an index cancer to whose frequency the frequency of other cancers could be compared. Hence efforts should be made to bring to light data on this cancer from different countries of the world. It has also been shown that bilateral retinoblastoma survivors may be more likely to develop another primary malignant neoplasm than any other cancer patients. It is proposed to estimate the incidence of other malignant neoplasms in retinoblastoma patients and their relatives. The data will be collected from Finland, with the pathology laboratory of the Helsinki University Eye Hospital serving as the main source of information.

EPIDEMIOLOGICAL STUDY ON WORKERS EXPOSED TO CHLOROMETHYL-METHYL ETHER (CMME) AND BIS-CHLOROMETHYL ETHER (BCME)

B. Terracini, Universita degli Studi di Torino, Istituto di Anatomia e Istologia Patologica, Dept. of Pathology, *Via Santena 7, I10126 Turin, Italy*
In the Montedison plant in Castellanza (Varese, Italy) CMME was used in the manufacture of ion-exchange resins during 1946-63 and it has been used in the laboratory since that time. In addition, in several areas of the plant the concurrent presence of formaldehyde and HCL (precursors of BCME) has been observed. The number of workers employed since 1946 in the plant is about 2,500. Deaths are being traced through the records of the town of birth of each worker. Mortality rates will be related to the length and sector of work in the plant and compared to those of the general population in the province of Varese.

ANTHROPOLOGICAL, FAMILIAL AND PRENATAL FACTORS IN HEMOPOIETIC SYSTEM NEOPLASMS

E. Quiroga Michao, Grupo Argentino Cooperativo de Estudios Epid. en Hematologia, *Las Heras 1895, 1127 Buenos Aires, Argentina*
Differences in mortality rates for these neoplasms have been observed among the different immigrant groups in Argentina. Preliminary results of a case-control study carried out on 603 case-control pairs show: (1) Fewer cases of acute non-lymphocytic leukemia and Hodgkin's disease in Spaniards, and more cases of lymphoproliferative disorders in Spaniards and of Hodgkin's disease in Italians; (2) acute non-lymphocytic leukemia cases had fewer Spanish ancestors and cases of lymphoproliferative disorders had fewer Paraguayan, Chilean and Bolivian ancestors; (3) fewer cases of acute lymphocytic and non-lymphocytic leukemia had green eyes, and among the latter cases there were fewer people with blue and grey eyes; (4) there were no differences in the proportional mortality caused by cancer or hemopoietic system neoplasms between relatives and spouses; (5) among the cases it was observed that fewer patients were born by young mothers and fewer were first born. The differences were observed both in children and in adults. No differences were observed in other prenatal factors. The study continues.

3.2631,
THE EFFECT OF EXOGENOUS ESTRIOL AND ANTIESTROGENS ON BREAST CANCER INCIDENCE

M.A. Basombrio, Academia Nacional de Medicina, Inst. de Investigaciones Haematologicas, Seccion Leucemia Experimental, *Pacheco de Melo 3081, 1425 Buenos Aires, Argentina*
Previous work has shown that full-term pregnancy before 25 years of age significantly reduces the incidence of breast cancer in women. The possible mechanism underlying this observation may be that the high production of oestriol which occurs during pregnancy could block cell receptors for the more 'carcinogenic' oestrogens, oestrone and oestradiol. The observation that oestriol prevents chemically induced mammary cancer in rats (Lemon, H.M.; Cancer Res. 35: 1341, 1975) poses the question of whether exogenous oestriol given early in life may prevent mammary cancer in women. A registry of women who are at high risk of developng first or second breast cancer, consisting of first order relatives of breast cancer patients and patients with unilateral breast tumor who have been 'cured' surgically, is being set up. Using this high-risk population, it is anticipated that the time normally required for a prospective study on the occurrence of the disease as a consequence of environmental factors will be more than halved. Particular attention is paid to the effect that administration of oestriol and/or antioestrogens may exert upon breast cancer incidence. The study is being organized as an inter-hospital registry which will record data on high-risk factors, parity and oestrogen treatments.

DIAGNOSTIC AND ETIOLOGICAL IMPLICATIONS OF MAMMOGRAPHIC CALCIFICATIONS IN BREAST DISEASE

D.V. Vakil, University of Toronto, Faculty of Medicine, Dept. of Preventive Medicine & Biostatistics, *92 College St., Toronto, Ontario, Canada* M5S 1A8
The presence of multiple punctate calcification in the breast and its association with breast carcinoma has been reported by many investigators. In the course of clinical mammography during the past several years we have detected calcifications in numerous cases of carcinoma of the breast and, in many of these, the presence of calcification on the mammogram in the absence of a palpable mass was the only sign of carcinoma. We have obtained genetic, epidemiological, pathological, and radiological information on 2,338 women who were radiographed for clinical indications of breast disease at the Toronto Western Hospital from 1968 to 1973. Biopsies or mastectomies were done for surgical or radiological suspicion of malignancy in these women. The biopsies indicated that 354 women had breast cancer, 1,713 had benign breast disease, and 272 had no apparent breast disease. We are studying the genetic, epidemiological, pathological, and radiological factors in those diagnosed as having breast cancer, those who had benign breast disease, and those without apparent breast disease. From the available pathological and radiological information on these women, we are also determining if a certain pattern of calcification correlates with (1) the presence of breast cancer, (2) the type of breast cancer, and (3) the type and degree of fibrocystic disease if carcinoma is not diagnosed pathologically.

THE POPULATION STUDY IN GLOSTRUP OF MEN AND WOMEN BORN IN 1914

M. Schroll, Kobenhavns Amts Sygehus Glostrup, Inst of Preventive Medicine, *2600 Glostrup, Denmark*
The Glostrup population study of 60 year olds in 1974 was an epidemiological investigation of a cohort delimited by age and geographical conditions, which had been investigated previously in 1964. The investigation illustrates risk factors for arteriosclerotic cardiovascular disease in a Danish population, but many variables are registered at 50 and 60 years and interrelations found. In 1974, 15 men and 10 women of the originally investigated 514 men and 461 50 year old women had died from cancer. In 1974, all cancer diagnoses and treatment given during the ten years were registered. All participants were given a thorough clinical examination including X-rays of thorax and spine and all women had a vaginal smear taken. The cohort will be followed.

NATURAL HISTORY OF POSTMENOPAUSAL BREAST CANCER

F. De Waard, Rijksuniversiteit te Utrecht, Inst. of Social Medicine, *Bijhouwerstraat, NL-2501, Utrecht, Netherlands*
Population screening for breast cancer (palpation, xeroradiography) of 20,000 women 50-64 years of age, at regular intervals (12-18 months) will enable the investigators to study factors which determine incidence and growth rates of preclinical breast cancer occurring after menopause. Particular attention will be paid to endocrine and nutritional factors. Urine is being collected for determination of 11-deoxy-17-ketosteroids and frozen for future research (prospective study). Body weight and height and skinfolds are being measured. Blood pressure is taken and data on antihypertensive drug treatment and other possible risk factors are being collected. Blood samples are being taken at the second examination.

EPIDEMIOLOGY OF MESOTHELIOMA IN DOCKYARD WORKERS IN DEVONPORT, UNITED KINGDOM

M.M. Wagner, Medical Research Council, Pneumoconiosis Unit, Dept. of Pathology, *c/o Llandough Hospital, Penarth CF6 1XW, Wales, United Kingdom*
About 10 cases of pleural mesothelioma occur each year in workers previously exposed to asbestos in Devonport dockyard. This is a prospective study relating the disease to previous exposure and to histopathological and immunological changes. It is hoped to identify any high-risk groups within this population including those who have already developed some form of asbestos related disease.

PROSPECTIVE STUDY OF ROLE OF FECAL BILE ACIDS AND NUCLEAR DEHYDROGENATING CLOSTRIDIA IN LARGE BOWEL CANCER

A.P. Haines, Medical Research Council, Dept. of Health & Social Security, Epidemiology & Medical Care Unit, *Watford Rd., c/o Northwick Park Hospital, Harrow HA1 3UJ, England, United Kingdom*
The aim is to determine the role of faecal bile acids (FBA) and nuclear dehydrogenating clostridia (NDC) in the aetiology of cancer of the larger bowel. About 7,500 men and women aged 45-74 are being recruited into the prospective study; stool samples are collected from each participant, and stored at low temperature. All participants are then followed up for a minimum of five years. The stool samples from those developing large bowel cancer and from two or three matched controls for each new case will then be analysed for FBA and NDC. Breath methane estimations are also being carried out on about half the total study population, as it has recently been shown that a higher proportion of patients with large bowel cancer have detectable levels of breath methane than patients with other diagnoses.

AN INVESTIGATION INTO ORAL CANCER AND ORAL PRECANCEROUS LESIONS IN INDIAN RURAL POPULATIONS IN RELATION TO TOBACCO HABITS

F.S. Mehta, Tata Inst. of Fundamental Research, Basic Dental Research Unit, *Homi Bhabha Rd., Bombay 400005, Maharashtra, India*

Oral cancer is one of the most common forms of cancer in India. There is a strong belief that such cancer may be preceded by certain white lesions in the oral cavity, which are thus termed precancerous. It is known, mostly through hospital-based studies, that oral tobacco habits are associated with oral cancer and precancerous conditions. The main objectives of the present study are to (1) investigate the degree of association between tobacco habits, oral cancer and precancerous conditions, and (2) elucidate the natural history of oral precancerous conditions from clinical and histological viewpoints. The study design is prospective in nature. In a first survey in 1967-1968, in five districts in different parts of India where different tobacco habits prevail, 50,000 individuals were interviewed about their tobacco habits and examined for the presence of oral precancerous conditions. Since 1969 these individuals have been followed up annually, clinically, histologically, and cytologically, for change of habits and development of oral precancerous conditions. Follow-up surveys comprising a period of 10 years have been completed. A comprehensive report on the follow-up study is now under preparation.

INVESTIGATIONS OF ORAL CANCER AND PRECANCEROUS CONDITIONS

F.S. Mehta, Tata Inst. of Fundamental Research, Basic Dental Research Unit, *Homi Bhabha Rd., Bombay 400005, Maharashtra, India*

Oral cancer is the most common form of cancer in India. It is said to be frequently preceded by white lesions termed precancerous lesions. Two studies are carried out to elucidate the natural history of these oral precancerous lesions and their association with tobacco usage. About 100,00 individuals residing in Ambegaon and Junnar Taluks of Poona districts were examined for the presence of oral precancerous lesions and tobacco usage habits. The individuals with lesions and suitably matched controls are now followed up annually. About 4,000 Bombay policemen were examined in 1959 for the presence of oral precancerous lesions and tobacco usage habits. These policemen are re-examined at five-year intervals. Three follow-ups have been completed and the fourth one is now being planned.

INCREASING RISK FOR BREAST CANCER - ASSOCIATION WITH FAMILIAL, GENETIC AND REPRODUCTIVE FACTORS

N.E. Day, Centre International de Recherche sur le Cancer, Epidemiology & Biostatistics Unit, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France*

OBJECTIVE: To determine whether there are hereditary characteristics which might be of use in the identification of women having a high risk of developing breast cancer. The unique facilities available in Iceland for the study will be utilized. These include (1) a nationwide cancer registry functioning since 1954 (about 800 cases); all cases of breast cancer diagnosed between 1910 and the start of the cancer registry are on file, (2) a computer-based National Roster since 1952, (3) a family linkage file linking every individual alive after 1910 to his parents and children, and (4) a cervical screening clinic which has seen more than 80% of the female population in Iceland born between 1905 and 1945. Information is collected on reproductive history and age at menarche, to be used as control data. If an excess risk is found, an effort will be made to (1) correlate familial risk with recognized epidemiological risk factors for breast cancer, (2) quantify the risk attached to different types of relationships, and (3) for each class of relative, examine the association, if any, between the degree of risk and the age of the proband case and age of appearance of cancer among these relatives.

COMPARISON OF THE EFFECTS OF PLAIN AND FILTER CIGARETTE SMOKING UPON THE INCIDENCE OF LUNG CANCER

J. Rimington, North Western Regional Health Authority, Greater Manchester Mobile Chest X Ray Service, *Shaw Heath, c/o St. Thomas Hosp., Stockport SK3 8BL, England, United Kingdom*

OBJECTIVES: To: (1) determine smoking habits in relation to the amount and type of cigarettes smoked (filter or plain); (2) ascertain the lung cancer incidence over a period of at least four of five years; and (3) relate lung cancer incidence to type of cigarette smoked.

METHODS: Large numbers of male mass radiography volunteers, at least 40 years of age, have been questioned and answers recorded on special forms. Subsequent X-ray examinations have excluded men with existing lung cancers. Yearly follow-up will be accomplished by comparing notifications of lung cancer cases of the Manchester Regional Cancer Registration Bureau with these special forms. Most deaths from lung cancer are registered even if the cases have not been registered before death. Information on smoking habits has been computer processed.

ENVIRONMENTAL AND OCCUPATIONAL FACTORS AND DISTRIBUTION OF LUNG CANCER AND BRONCHITIS IN UMBRIA

A. Candeli, Universita degli Studi di Perugia, Faculty of Science, Institute of Hygiene, *via del Giochetto, Perugia, Italy*

Umbria is one of the central regions of Italy. Some areas of this region are very different from others with respect to economic and social development, kinds of industries, density of population and climate. These differences are especially marked between the two biggest cities of the region, Perugia and Terni. Preliminary studies have shown that mortality from lung cancer and from bronchitis is higher in Terni than in Perugia. Research is in progress on atmospheric pollution in these towns which seems higher in Terni than in Perugia. For this reason it is proposed to study retrospectively the mortality and the morbidity from lung cancer and bronchitis in the two cities in relation to environment and occupation.

DISTRIBUTION OF SITE-SPECIFIC CANCER MORTALITY IN AUSTRALIA

N.D. McGlashan, University of Tasmania, Dept. of Geography, *P.O. Box 252C, Hobart, Tasmania 7001, Australia* (00438)

The objective of the study is to utilize death certification to define stochastic and geographical internal variations of cancer mortality within Australia. A particular feature is the use of probability testing to assess significantly high and low incidences by area. Hopefully this will be followed by local inquiry towards explanation. A preliminary publication appeared in Medicine, Biologie, Environment, 4, 85-97, 1976.

MESOTHELIOMA REGISTER

H.T. Planteydt, Pathologisch Anatomisch Laboratorium, *Noordpoortplein 2, Middelburg, Netherlands*

In order to obtain information about the frequency of mesothelioma of pleura, peritoneum and pericardium, from 1969 onwards, all pathologists in the Netherlands were asked to cooperate in the registration of all histologically verified cases. These results are compared with the data of the Central Bureau of Statistics. In many cases slides and/or tissues were available: in a limited number of cases, electron microscopical investigations of lung tissue were done for asbestos. The occupational history was investigated extensively. Many cases are reviewed by a mesothelioma committee (Planteydet, de Jagar, van der Schoot). The geographical distribution, relation to occupational history and exposure to asbestos are recorded in several ways. From 1976 onwards registration, together with the other investigations, follows the same lines as the mesothelioma register in the United Kingdom. Since 1976 collaboration with other mesothelioma registers in the EEC has been established.

REGIONAL DIFFERENCES OF AND TIME TRENDS IN CANCER MORTALITY IN POLAND

J. Staszewski, Inst. of Oncology, Cancer Epidemiology Unit, *Armii Czerwonej 15, 44100 Gliwice, Poland*

The aim of the study is to uncover and describe patterns in the geography and dynamics of cancer in Poland. This is necessary for studies of the suspected aetiologic factors, as well as for monitoring the changes in cancer frequency. Cancer mortality data by primary site, age, sex, and residence are being collected, starting with calendar year 1970. Age-specific and age-adjusted rates have been computed

and analyzed for the total country, for urban and rural areas, and for each of the 22 districts for the period 1970-1974.

EPIDEMIOLOGICAL AND CLINICAL ASPECTS OF STOMACH CANCER

T. Popiela, Akademia Medyczna w Krakowie, Surgical Clinic, Dept. of Gastroenterology, *Ul. Pradnicka 37, 31202 Cracow, Poland*

The aim of the studies is to set up the criteria for the early detection of stomach cancer, to evaluate the effectiveness of different treatment methods, to learn the natural history of the disease in the population. The project will cover epidemiological as well as clinical aspects. An epidemiological study will be made in an industrial population of about 10,000 workers. On the basis of a screening questionnaire and endoscopy the risk-group will be followed-up by a yearly health examination. In addition a case-control study will be conducted on hospital patients. A mortality study on stomach cancer in different subgroups of a population in the Kracow region has begun.

3.2653,
EPIDEMIOLOGY OF LEUKEMIA AND APLASTIC ANEMIA

K. Aoki, Nagoya University, School of Medicine, Dept. of Preventive Medicine, *65 Tsurumai-cho, Showa-ku, Nagoya 466, Aichi ken, Japan*

Japanese immigrants to Hawaii and their descendants have experienced a much higher mortality rate from leukemia and lower mortality from aplastic anemia than indigenous Japanese, reaching a mortality level similar to the Caucasians. There is no statistically significant difference in the sum of the age-adjusted mortality from all bone marrow diseases (ICD 280-289, ICD 205-209) except for lymphatic leukemia between Japanese Americans and indigenous Japanese. Genetico-epidemiological study has shown that consanguinity among aplastic anemia cases and leukemia cases was significantly more frequent than in the general population. The above data suggest that not only environmental factors but also host factors affect the incidence of these diseases.

CASE-CONTROL STUDY OF ETIOLOGICAL FACTORS IN CANCER AND OTHER TUMORS OF THE BREAST

J. Staszewski, Inst. of Oncology, Cancer Epidemiology Unit, *Armii Czerwonej 15, 44100 Gliwice, Poland*

This is a study of the environmental and host factors in the development of breast cancer and also of benign breast tumors, such as chronic cystic disease and fibroadenoma in a population in which the frequency of breast cancer is lower than in other western countries but appears to be increasing substantially. Both cases and controls consists of the inpatients of the Oncological Inst. in Gliwice, residents of Silesia, interviewed since late 1965. Some of the results have been published. They relate to age at menarche (JNCI 47, 935-40, 1971), childbearing and breast feeding (Pol. Tyg. Lek. 29, 1329-32, 1974), past and co-existent diseases (Nowotwory 26, 201-4, 1976), and body build (Prev. Med. 6, 410-15, 1977) and benign breast diseases (Nowotwory 29, 213-221, 1979).

CASE-CONTROL STUDY OF MORBIDITY IN UNITED STATES CARBON BLACK WORKERS

J.M. Robertson, University of Western Ontario, Faculty of Medicine, Dept. of Preventive Medicine & Epidemiology, *1151 Richmond St., London, Ontario, Canada* N6A 3K7 (02468)

This study aims to determined if carbon black workers who contracted selected circulatory, malignant and respiratory diseases had higher exposure to carbon black than did control workers who remained free of these diseases. Seven of the eight companies that are members of the Carbon Black Industry Committee for Environmental Health searched the records of their health insurance plans for cases of the selected diseases. Two contol workers will be selected for each case, one matched on age (plus or minus 2.5 years) and one matched on age and years of service (plus or minus 2.5 years). The exposures of the cases and controls will be estimated from their work histories in the carbon black industry. The exposure levels of the cases will be compared with those of the controls to determine if any differences are evident.

EPIDEMIOLOGICAL STUDY OF ACUTE LEUKEMIA IN ADULTS AND CHILDREN (ABBREV)

J.E. Parker, Lions Gate Hospital, *E. 13th St., Vancouver, British Columbia, Canada* V7L 2L7

In a retrospective study, an association between cases of acute leukemia in some adults and between other cases of leukemia in childhood or in other adults has come to light within the suburban community of North and West Vancouver, there being a variable and sometimes long latent period between cases. A prospective questionnaire study of all newly diagnosed cases of acute leukemia within the above suburban community is being carried out, attempting to define a relationship between cases as to time, place and person. This is considered under the following headings: date of diagnosis, age, sex, duration of symptomatology, family history of malignancy, contact with other cases of lymphoreticular malignancy in family or friends, addresses and change of address (domestic and employment) within the above community, exposure to domestic animals. It is proposed to compare these findings with data on age matched controls i.e. non-leukemic cases admitted to Lion's Gate Hospital.
